Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Dr. Carver Dies—George Washington Carver, D.Sc., since 1896 a member of the staff of the Tuskegee Institute, Tuskegee, died at his home on January 5 at the institute, aged 78. He had been in ill health for some months and was confined to his bed for ten days preceding his death. Dr. Carver, at the time of his death, was director of the department of agricultural research at the institute and, since 1935, had been coordinator in a survey conducted by the division of mycology and diseases, Bureau of Plant Industry, U. S. Department of Agriculture. He had studied at the high school in Minneapolis, Kan., graduating in 1894 at the Iowa State College of Agriculture and Mechanic Arts, Ames.

CALIFORNIA

Human Case of Plague—A case of human plague in a child 2½ years of age was reported in Siskiyou County recently. The onset of the disease was about November 8. The diagnosis was confirmed at the U. S. Plague Laboratory, San Francisco.

Purple Heart Cross Awarded to Dr. Rogers—Dr. Henry S. Rogers, Petaluma, formerly president of the California Medical Association, recently received the purple heart cross on order of the adjutant general's office in Washington, D. C., "for meritorious army service" in World War I and in recognition of "injuries received in action Sept. 26, 1918 in the Argonne forest on Vauxhill."

Medical Care of Strangers—The San Francisco County Medical Society recently instituted a twenty-four hour service through which any person entering San Francisco, who has no private physician, may be referred to one of its members. The office of the society has been furnishing lists of five names to any one inquiring for a physician between the hours of 9 a. m. and 5 p. m. Recently, however, through the aid of one of the direct wire exchanges, the same service has been instituted between the hours of 5 p. m. to 9 a. m. The names are taken in rotation from the list of members of the society who have signified their willingness to serve.

Dr. Pinkham to Retire as Secretary of State Board—Dr. Charles B. Pinkham, San Francisco, secretary-treasurer of the California Board of Medical Examiners since 1913, will retire from this position in February when he reaches the mandatory age limit for leaving state service according to *California and Western Medicine*. He will continue as a member of the board. At a recent meeting of the board he was reelected secretary. Other officers are Drs. Percival Dolman, San Francisco, president, and George Thomson, Los Angeles, vice president. Dr. Pinkham graduated at the New York Homeopathic Medical College and Hospital in 1899.

Physicians Needed—The Los Angeles County Civil Service Commission announces vacancies for the position of a physician and of an autopsy surgeon. Applicants for the physician's position, which pays from \$235 to \$270 a month, must have a degree of medicine and must have completed a one year internship in an approved hospital. In addition to these qualifications, the applicants for the position of autopsy surgeon with a starting salary of \$235 a month, must have at least two years of professional experience in the pathology laboratory of an accredited hospital, medical school or public agency. There will be no written examination for this position. Candidates will be rated on their professional training and experience and on their ability and personal suitability for work as an autopsy surgeon as evidenced by investigation or interview. There are no residence requirements for either position and no age limitations for the duration of the war. Interested persons should obtain full information and file an application at Room 102, Hall of Records, Los Angeles, on or before January 25 for the physician's position and on or before February 5 for the position of autopsy surgeon.

New Surgical Essay Contest—The San Francisco Surgical Society announces the inauguration of an annual contest in the field of general surgery for young physicians in San Francisco and vicinity. First prize is \$150 and second prize \$100. The author must be a physician in the field of general surgery who is in the period of graduate training not more than six years removed from graduation from medical school. The paper submitted must represent original work in the field

of experimental or clinical surgery but not necessarily based on an original idea. The author may be aided by associates. The paper must not have been presented or printed, as submitted in its final form, prior to its submission to the society. All papers must be received by the secretary of the society, Dr. John W. Cline, 490 Post Street, San Francisco, and the return address must also be that of the secretary of the society. Papers must be submitted without marks that would identify the author, hospital or institution of origin, and a sealed non-transparent envelope enclosing the name and address of the author must be furnished. If the papers are published they shall be designated as the prize winning essays of the San Francisco Surgical Society.

COLORADO

First Training School for Control of Cancer—The Colorado Society for the Control of Cancer held its first training school for city and district chairmen in Denver, Dec. 9-10, 1942, under the direction of Mrs. Emily G. Bogert, state commander, Women's Field Army. Among the speakers were:

Dr. Charles Smith, Relationship of Colorado Society to the American Society for the Control of Cancer, the Colorado Medical Society, and Public Health.
Dr. William W. Harkett, Organization and Function of a Cancer Clinic.
Dr. Roy I. Cleere, Cancer a Public Health Problem.
Dr. John S. Bouslog, Diagnosis and Treatment of Cancer.
Dr. Edward J. Meister, Importance of Follow Up Work in Cancer Control.
Dr. Osbourne S. Philpott, Cancer Education in the Control of Cancer.
Mrs. Mary H. Emberton, The Nurse in Cancer Control.
Lieut. Col. Wallace D. Hunt, Regional Medical Officer, Seventh Service Command, subject not announced.

The objectives of the school were to afford a background for cancer control, understanding of cancer control needs, over view of cancer organizations and a knowledge of cancer control program activities.

CONNECTICUT

Physiologist Goes to McGill—Dr. Heihel E. Hoff, associate professor of physiology at Yale University School of Medicine, New Haven, has been appointed professor of physiology at McGill University, Montreal. The appointment was effective Dec. 1, 1942.

DISTRICT OF COLUMBIA

Course in Ocular Surgery—George Washington University School of Medicine, Washington, announces a postgraduate course in ocular surgery, pathology and orthoptics to be given February 15-20. Additional information may be obtained from the secretary, Miss Louise Wells, 927 Seventeenth Street N.W., Washington, D. C.

ILLINOIS

New Advisory Members on Cancer Control—Governor Green recently appointed the following as members of the advisory board to the division of cancer control in the state department of public health: Drs. Frankleroy Flinn, Decatur; James Scott Templeton, Pinckneyville; Edwin F. Hirsch, and James P. Simonds, Chicago, and William M. Cooley, Peoria. Unexpired terms are those of Drs. Roswell T. Pettit, Ottawa, and John A. Wolfer, Chicago.

Course on Psychoanalysis and Psychosomatic Medicine—The Institute for Psychoanalysis opened at the University of Illinois a course on the fundamentals of psychoanalysis and psychosomatic medicine, January 13. The series of lectures, which will be held on Wednesdays through May 26, will cover the following subjects: The nature of psychologic understanding, historical development of the fundamental concepts of psychoanalysis, the fundamentals of psychodynamics. The principle of merit and the principle of surplus, the fundamentals of psychodynamics, continued (repression, regression, fixation, reaction formation, projection, rationalization, substitution), the process of biologic and psychologic maturation, theory of dreams, development and structure of the personality, psychoanalytic theory of neuroses and psychoses, the principles of psychosomatic medicine, principles of psychoanalytic therapy (adult analysis), other therapeutic applications of psychoanalysis (brief psychotherapy, child analysis, treatment of psychoses).

Chicago

The Christian Fenger Lecture—William H. Taliaferro, Ph.D., Elrakim Hastings Moore Distinguished Service professor of parasitology and dean of the division of biological sciences, University of Chicago, will deliver the sixth Christian Fenger Lecture of the Institute of Medicine of Chicago and the Chicago Pathological Society, February 8, at the Palmer House. His subject will be "Antigen-Antibody Mechanisms in Immunity to Metazoan Parasites."

INDIANA

Secretaries' Conference—The annual secretaries' conference of the Indiana State Medical Association will be held at the Indiana World War Memorial, Indianapolis, January 24. The speakers will include

Dr. John H. Fitzgibbon Portland Ore Oregon Medical Service and Situation in Kaiser Shipyards
Mr. Rollen W. Waterson Gary executive secretary Lake County Medical Society Lake County All Out Medical Plan
Dr. Albert S. McCown, Washington D. C. Red Cross Activities and Medicine
Dr. Harold S. Diehl Minneapolis 1943 Program of Procurement and Assignment Service for Physicians
Dr. Charles R. Bird Indianapolis Indiana Doctors Carry On
Dr. Carl Peterson Chicago Industrial Health and the War Emergency

At the dinner session, Brig Gen David N. W. Grant M. C., U. S. Army, Washington, D. C., will discuss "Aviation Medicine and Victory," and Brig Gen Fred W. Rankin M. C., U. S. Army, Washington President American Medical Association, "American Medicine at War."

KANSAS

Changes in Health Officers—Dr. Daniel C. Barrett formerly of Bloomington, Ind., has been detailed by the U. S. Public Health Service to serve as health officer of Montgomery County, with headquarters in Independence.—Dr. Garfield A. Reutter, formerly of Bigfork, Minn., is the new health officer of Cherokee County.

Salina First City in State to Pass Restaurant Ordinance—Salina is the first city in the state to pass the U. S. Public Health Service Standard Restaurant Ordinance sponsored by the state board of health. The ordinance regulates eating and drinking establishments and was passed by Salina to control sanitation conditions brought about by the establishment of military centers. The food and drugs division will aid in enforcing the ordinance until it is in complete operation, according to the *Neus Letter* of the state board of health.

MARYLAND

Night Chest Clinics Opened—The Baltimore City Health Department recently opened its third diagnostic chest clinic on the fifth floor of the Druid Health Center. The new clinic is for members of the Negro race. Another clinic is for white and Negro patients and one is for white patients only. The city department of health introduced a new night service in these clinics on December 1.

Lewis H. Steiner Fund—The late Dr. Walter R. Steiner has made the Medical and Chirurgical Faculty of Maryland the residuary legatee of his estate as a memorial to his father. Dr. Lewis H. Steiner of Frederick and Baltimore. A trust fund will be designated the Lewis H. Steiner Fund, the income of which will be used "in perpetuity for the purchase of medical periodicals and of books and monographs dealing with special branches of medicine or surgery." Dr. Steiner also gave his medical books to the association. Dr. Lewis H. Steiner was an active member of the faculty after the period from 1855 until he became librarian of the Enoch Pratt Free Library in 1884. During the Civil War he was chief inspector, U. S. Sanitary Commission, Army of the Potomac. In 1856 he delivered the annual oration before the Medical and Chirurgical Faculty on "The Physiological Properties and Chemical Detection of Strychnia." Many rare and valuable volumes are included in the late Dr. Walter Steiner's gift, which represents a collection of forty years.

MINNESOTA

Physician Awarded Distinguished Service Cross—Capt William Wilmerding Moir Jr., M. C., U. S. Army, formerly of Minneapolis, has been awarded the Distinguished Service Cross for extraordinary heroism in action in Northern Africa. According to the *Bulletin* of the Hennepin County Medical Society, Captain Moir, together with members of his paratroop unit, was shot down in a plane near Oran on November 8. His citation reads "During the attack in the air and the ensuing strafing on the ground, Captain Moir distinguished himself by extraordinary heroism against the armed enemy by inspiring administration of medical attention to wounded personnel before attention to himself, despite severe wounds to his head and back."

Abortinist Sentenced—On January 2 Sophia Peck Minneapolis, aged 62, was sentenced by Judge Frank E. Reed of the District Court of Hennepin County to a term of not to exceed four years of hard labor at the Women's Reformatory at Shakopee. Mrs. Peck had been convicted by a jury Dec. 3, 1942. The testimony at the trial showed that the defendant attempted to perform an abortion on an unmarried Minneapolis

girl on July 17, 1942 by the use of a rubber catheter. The attempted abortion was a failure and the same procedure was repeated again on September 19 and 24. The patient became seriously ill and was hospitalized twice in October. She subsequently recovered and testified for the state at the trial. The state also had as evidence catheters, instruments and medicinal preparations seized by the Woman's Bureau of the Minneapolis Police Department at the time the defendant was arrested. The defendant told the court that she was a tailor by occupation but had also engaged in the selling of cosmetics. She holds no license to practice any form of healing in Minnesota. Mrs. Peck was tried for a similar offense in October 1937 but was found not guilty by a jury.

NEW YORK

Postgraduate Lectures—The following series of lectures on general medicine will be presented before the Columbia County Medical Society at the Hudson City Hospital, Hudson.

Dr. Clarence E. de la Chapelle New York March 11 Management of Acute Cardiovascular Emergencies
Dr. Norman H. Plummer New York March 25 Newer Chemotherapeutic Methods
Dr. J. Maxwell Chamberlain Oneonta April 8 Benign and Malignant Neoplasms: Diagnosis, Clinical Effects and Treatment
Dr. Harvey B. Matthews Brooklyn April 22 Pelvic Tumors Complicating Pregnancy, Labor and the Puerperium
Dr. Marjorie F. Murray Cooperstown May 6 The Physical Examination of the Child: Its Importance in Diagnosis

Dr. Abraham C. Silverman, Syracuse gave a lecture on "Preventive Pediatrics and the Periodic Health Examination" before the Cortland County Medical Society, January 15. These and similar lectures are offered under a cooperative program between the state medical society and the state department of health.

New York City

Anniversary Discourse of Academy of Medicine—Sir Norman Angell, London, author and lecturer will deliver the anniversary discourse of the New York Academy of Medicine January 28, on "The Scientific Method and the World Crisis." The lecture is one of a series of "lectures to the laity," announced in *THE JOURNAL*, Oct. 31, 1942, page 708.

Atypical Pneumonia and Keratoconjunctivitis Now Reportable—At a meeting, January 12 the city department of health added to its list of reportable diseases those of primary atypical pneumonia and keratoconjunctivitis. The action was taken because primary atypical pneumonia, also known as virus pneumonia, is reported to be increasing throughout the country and because of the widespread distribution of keratoconjunctivitis in an epidemic form.

Lisa Award for Research in Medicine—The Alumni Society of the New York City Hospital, Welfare Island has established the James R. Lisa Award to be given for meritorious work in research medicine done in the laboratories of the hospital under Dr. Lisa's direction. The award to be made by Dr. Lisa at appropriate times to the worker deemed by him to be worthy of it. The prize will consist of a medallion or parchment and an honorarium of several hundred dollars. Dr. Lisa, who graduated at the University of Michigan Medical School, Ann Arbor, Mich., in 1914, is an alumnus of and pathologist to the New York City Hospital, Welfare Island.

Courses for Training in Kenny Method—The National Foundation for Infantile Paralysis announces that courses of instruction in the Kenny method of treatment for infantile paralysis will be given at the school of education of New York University in cooperation with the college of medicine. The course for physical therapists will be arranged on a part time basis and will continue throughout the semester starting February 3. Registration will be limited to those who are members of the American Physiotherapy Association or the American Registry of Physical Therapy Technicians. Other graduates of recognized schools of physical therapy will be admitted only on special consideration of the qualifications of the applicant. Instructions for physicians and nurses will be offered later. Further inquiries concerning the courses should be directed to Dr. George G. Deaver, School of Education, New York University.

Maey Foundation to Finance Tropical Medicine Research—A five year program of research and teaching in tropical medicine will be launched soon at the Columbia Presbyterian Medical Center with the aid of a \$150,000 grant from the Josiah Macy Jr. Foundation. According to the *New York Times* the program has been formulated to meet "a great responsibility of this country to train doctors and students in tropical medicine." A regular department of tropical medicine will be set up in the De Lamar Institute of Public Health, a division of the medical school of Columbia. The institute is housed in the Washington Heights Health Center. It is

expected that the medical center and the city's health department will cooperate in the new project. Existing laboratory and clinical facilities will be used and the staff of the bacteriology and parasitology laboratories of the various clinical departments will join in the new work. The *Times* also reported that Columbia is endeavoring to obtain the services of the leading men in the tropical field, including a director for the program. Columbia maintains a school of tropical medicine at the University of Puerto Rico, San Juan. This school will be used as a field station whose work will be coordinated with the program in New York. After completing their training in New York, medical personnel will receive additional field training at Puerto Rico and other points throughout the world. In a statement to the press Dr Wilford C. Rappleye, dean of the Columbia University College of Physicians and Surgeons, New York, said that after the war there will be a tremendous amount of tropical diseases in this country as the result of members of the armed forces returning in large numbers from countries where tropical diseases are widespread. Such areas as Africa, the Solomon Islands, New Guinea, India and Burma were listed as places from which soldiers, sailors and marines will undoubtedly transport diseases. Malaria and dysentery will be the two principal diseases, he stated. The Macy foundation, which recently has concerned itself with medical research as it is related to difficult phases of the war, was established in 1930 by Mrs. Walter Graeme Ladd of Fair Hills, N. J., with an initial endowment of \$5,000,000 as a memorial to her father.

OHIO

Dr. Ruiz Studying at Health Museum—Dr. Manuel Uribe y Ruiz, who is director of the National Hygiene Museum, Mexico City, is taking a three-months internship at the Cleveland Health Museum at the suggestion of the Pan American Sanitary Bureau.

General Morgan Gives Morris Lecture—The sixth annual Roger S. Morris Memorial Lecture was delivered January 8 in the auditorium of the University of Cincinnati College of Medicine by Brig. Gen. Hugh J. Morgan, chief consultant in medicine to the surgeon general of the U. S. Army, Washington, D. C. General Morgan's subject was "Reflections of an Irregular Army Medical Officer."

Twenty-Eight Years as Society Secretary—Dr. Alexander S. McCormick, Akron, has retired as secretary of the Summit County Medical Society after holding the position for twenty-eight years. Dr. McCormick, who graduated at the Western University Faculty of Medicine, London, Canada, in 1911, served as secretary of the county medical society from 1913 to 1918 when he refused reappointment. In 1921 he was named to the combined office of secretary-treasurer, serving in this capacity until 1940 when the position was separated. He has been secretary since 1940. He was historian of the society from 1919 to 1920. In 1926 he established the *Bulletin* of the society and served as editor and business manager until 1940. Dr. McCormick is still conductor of the Doctors' Symphony Orchestra, which he founded in Akron in 1926. Just recently he was appointed a committee of one to record the medical history of the society.

PENNSYLVANIA

Mr. Rowland Dies—Mr. Leslie W. Rowland, head of the medical textbook division of the J. B. Lippincott Company, died January 2 at his home in Swarthmore.

X-Ray Survey Among Union Workers—Twenty-two cases of tuberculosis were reported out of the first 1,564 persons given x-ray examinations in an effort to determine the extensiveness of tuberculosis among industrial workers carried out by the Erie County Health and Tuberculosis Association. The arrangement was made with the United Electrical, Radio and Machine Workers Local 506 for x-ray examinations of its members and their families using the rapid paper method. Most of the members were employed at the Erie plant of the General Electric Company. Of the total 14 were found with cardiovascular disease and 22 with other diseases. The analysis includes studies as to age, sex and occupation. According to the *Bulletin* of the Pennsylvania Tuberculosis Society, the study is being continued for other members.

Philadelphia

Dr. Eberhard Honored—The sixty-fifth birthday of Dr. Harry M. Eberhard, since 1925 professor and head of the department of gastroenterology, Hahnemann Medical College and Hospital, was observed with the dedication to him of the November-December issue of the *Review of Gastroenterology*.

Dr. Eberhard graduated at Hahnemann in 1898, serving as a member of the teaching staff since 1915 and as vice president of medical affairs since 1940. He has been associate editor of the *Review of Gastroenterology* since 1934.

Courses in Public Health and Preventive Medicine—The department of public health and preventive medicine at the University of Pennsylvania School of Medicine will begin a series of part-time courses sometime in February to cover such subjects as public health administration and communicable disease control. Each course will continue for six or eight weeks. On completion of one course another will be started in order that students may eventually complete all the work required for the master of public health degree. Philadelphia *Medium* points out that while the project is planned in response to requests from physicians it will be carried out only if the registration of physicians seems to justify the undertaking.

WEST VIRGINIA

New X-Ray and Laboratory Fee Schedule in Effect—On January 1 changes in the rules and regulations governing the handling of roentgenograms and the payment of x-ray and laboratory fees by the Workmen's Compensation Department went into effect. The new regulations provide that roentgenograms made by hospitals and physicians in connection with the treatment of compensable injuries must be labeled so as to show the date that the film was made, the claim number, the name of the claimant and the name of the employer and must be retained in the files of the hospital or of the physician making the same for a period of five years from the date of injury. They are to be furnished to the compensation commissioner on written request. Instead of making the x-ray films to the commission, the physician in charge of the case will now submit a full written report in triplicate together with the fee bill on which x-ray charges are made. The regulations further affect the number of roentgenograms and provide flat fees for blood transfusions, operations, anesthesia and laboratory work.

GENERAL

Meetings Postponed—The Association for the Study of Internal Secretions has indefinitely postponed its 1943 session which was tentatively scheduled to be held in Cleveland on April 5 and 6. The 1943 meeting of the Tri-State Medical Association of the Carolinas and Virginia will not be held.

Campaign Opens for Infantile Paralysis Funds—"Tomorrow's America Will Be as Strong as Today's Children" is the theme of the 1943 campaign to raise funds for the National Foundation for Infantile Paralysis. The drive opened on January 15 and will conclude with the annual celebration of President Roosevelt's birthday on January 30.

New Medical Director of National Drug Company—Dr. D. Olin Meeker, New York, has been appointed medical director of the National Drug Company. Dr. Meeker has been in general practice in New York and once served as head of the research department of Murray Breece Associates. Herman J. Schneiderworth, Ph.D., has been appointed director of the research laboratories of the company.

Safety Campaign Opened—On January 18 a national campaign was launched under the auspices of the War Production Fund to Conserve Manpower to stimulate interest in its program to reduce accidents. William A. Irvin, New York, national chairman of the fund, and Col. John Stilwell, New York, president of the National Safety Council, opened a lecture tour to take them to various places throughout the country where they will sponsor programs to focus interest on the national program to conserve manpower and reduce accidents.

Decrease in Holiday Deaths—Only ninety-four accidental deaths occurred in twenty-four states on Christmas Day as compared with 394 reported throughout the country on Christmas Day a year ago according to a nationwide survey by the Associated Press. The greatest decrease was in highway traffic deaths, fifty-two this year as compared with 301 in 1941. Two persons were killed in a railroad accident in Illinois, the rest of the deaths occurring in different ways. In Buffalo a 14-year-old girl was killed by an electric shock when an electric heater fell into a tub of water in which she was bathing. Another "freak" accident occurred in upstate New York when a man, chopping ice from the eaves of his house, fell to his death.

Dr. Schneider Honored for Work on Aviation Medicine—Edward C. Schneider, Sc.D., Middletown, Conn., since 1919 Daniel Ayres professor of biology at Wesleyan University and who during World War I, developed a physical fitness

index for testing pilots will be presented with the John Jeffries Award for 1942 by the Institute of Aeronautical Sciences at its "Honors Night Dinner" in New York, January 26. The award will be given to Dr. Schneider for his pioneering research in aviation and particularly for his development of the physical fitness index which has been used by the Army and Navy and in civilian aviation for more than twenty years. The award given annually "for outstanding contributions to the advancement of aeronautics through medical research" is named for Dr. John Jeffries, a Boston physician and the first American to make scientific observations from the air. Dr. Jeffries made his first aerial observations in 1784 from a balloon over London.

Board Examinations—The next examination of the American Board of Neurological Surgery will be held at the Illinois Neuropsychiatric Institute, Chicago, February 15 and 16. Dr. R. Glen Spurling, 404 Brown Building, Louisville, Ky., is the secretary. In view of transportation difficulties, the American Board of Psychiatry and Neurology, Inc., will hold regional examinations in May. Proposed places are Boston, Minneapolis, San Francisco, New Orleans and Ann Arbor. The exact time will be settled later, but the practical examinations will take place late in April and early in May, ending just before the meeting of the American Psychiatric Association in Detroit on May 10. One or more of the designated cities may be omitted from the schedule if less than twenty candidates apply for examination there. Written examinations will be given in March in each candidate's immediate vicinity as soon after March 1, the closing date for applications, as arrangements can be made. For details, communicate with the secretary, Dr. Walter Freeman, 1028 Connecticut Ave. NW, Washington, D. C.

Pharmaceutical Manufacturers' Award Goes to Dr. Doisy—Edward A. Doisy, Ph.D., professor and director of the department of biochemistry, St. Louis University School of Medicine, St. Louis, was presented with the annual award of distinction of the American Pharmaceutical Manufacturers Association at its annual meeting in New York, December 7. The presentation was made by Dr. Torald H. Sollmann, dean and professor of pharmacology and materia medica, Western Reserve University School of Medicine, Cleveland, "in recognition of Dr. Doisy's 'isolation in pure form of the female sex hormone estrone (theelin) and his other valuable contributions to knowledge of estrogenic substances important in therapy and research'." Dr. Sollmann's address of presentation was entitled "Those Busy Hormones." Other speakers included George R. Cowgill, Ph.D., New Haven, Conn., on hormone developments; Oscar Riddle, Ph.D., Cold Spring Harbor, N. Y., on hormone therapy; and Dr. Ephraim Shorr, New York, on the future of hormone therapy. In reply, Dr. Doisy gave a brief history of his experiments.

Children's Tumor Registry—The establishment of a Children's Tumor Registry at the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, has been announced. The project was developed under the auspices of the American Academy of Pediatrics to gather clinical case records under a single committee's supervision in the hope that enough data can be accumulated to warrant accurate conclusions for each of the many forms of childhood cancer from the following aspects: etiology and incidence; pathology of childhood cancer; difficulties in diagnosis; frequency and reasons for delay in diagnosis; average clinical course and response to various forms of therapy such as radiation and surgery. The varieties of case material include all malignant tumors, with Hodgkin's disease and leukemia; certain benign tumors, tumors that histologically are unusual; those so situated in the body as to endanger life or to be incompatible with it. All hospitals, clinics and members of the medical profession are urged to submit preliminary data on cases believed to be those of malignant tumors in children less than 15 years of age. If the preliminary review of these data indicates that the case is a proper one for acceptance, blank forms will be returned so as to obtain further details including roentgenograms and microscopic slides. If requested, the registry will obtain and forward immediately opinions by recognized authorities as to diagnosis and recommendation for treatment. The registry assumes the responsibility to collect and record follow-up data relating to the further clinical course and end results in all cases. All data and slides should be sent to the Memorial Hospital for the Treatment of Cancer and Allied Diseases, 444 East Sixty-Eighth Street, New York. The case records will be kept at the hospital until the executive committee of the American Academy of Pediatrics directs otherwise. Lieut. Comdr. Harold W. K. Dargeon, M.C.U.S., Navy pediatrician at the hospital, now on leave of absence

for war duty, originated the idea for the registry. A consulting board of pathologists will review the microscopical sections submitted to the registry. It is composed of Dr. Sidney Farber, Boston; Alvin G. Foord, Pasadena, Calif.; Howard T. Karnsner, Cleveland; Roy R. Kracke, Atlanta, Ga.; Robert A. Moore, St. Louis; John R. Schenken, New Orleans; Paul C. Steiner, Chicago; and Fred W. Stewart, New York. According to an announcement from the Memorial Hospital, cancer in children is a rare disease compared with that in the adult. On the other hand, the anatomic and histologic forms of malignant tumors which occur in children are more numerous than those which occur in adults. Furthermore, it was stated, the mortality rate of cancer during childhood is extremely high.

Traffic Deaths Show Decrease—About 28,000 traffic deaths have been reported on traffic death figures for the first eleven months of the year plus observed trends for December according to a statement from the National Safety Council. The estimate shows a decrease of about 12,000 as compared with the total of 39,969 reported for 1941. Despite the reduction, the council regards the 1942 toll as the greater blow to the nation's productive effort since it included among its dead almost 18,000 workers. The nation cannot feel too much satisfaction over the 1942 decrease because most of it resulted automatically from the decline in driving due to gasoline and tire rationing. From the standpoint of the national survey, the deaths of 18,000 irreplaceable workers and the injury of half a million more is a more serious loss than the larger casualty lists of previous years, it was stated. With national gasoline rationing and lower driving speed, the traffic death toll undoubtedly will decline still further in 1943. The council points out, however, that car pooling means more victims per accident. Progressive deterioration of tires, brakes and cars will increase the hazard. Reports show a definite increase in drinking drivers, it was stated. Any decrease in the 1943 total probably will be chiefly among nonworkers as in 1942. With more and more men, women and even children going into war work, traffic casualties among workers will be nearly as great as in 1942 unless police, engineers and the individual drivers and pedestrians do their utmost to prevent accidents. November traffic deaths totaled 2,260, a 43 per cent reduction from the 3,960 for November 1941. Even so, the November reduction did not equal the October drop of 49 per cent. The eleven month toll was 25,580, a 29 per cent drop from the 35,770 killed in the first eleven months of 1941. Travel during October, the most recent month for which figures are available, was 20 per cent below 1941. This was no greater than the September drop and is considerably smaller than the decrease in August. Except for the Mountain Region, whose relatively small death totals tend to fluctuate widely, the North Atlantic Region still had the smallest decrease in fatalities of any region. Its November drop was only 26 per cent against 51 per cent for the South Atlantic Region and 52 per cent in the South Central States. All of the states showed a decrease in traffic accidents for the first eleven months. Rural traffic fatality decreases exceeded urban drops by sizable margins for the eleven month period. November was no exception with cities showing an average fatality drop of 29 per cent as contrasted with a national decrease of 43 per cent. Rural deaths in November numbered only half as many as in November 1941. In the first eleven months of the year, urban fatalities dropped 16 per cent below the totals for the corresponding period in 1941. Rural fatalities decreased 36 per cent. Except for the very largest cities, those over 500,000, fatality decreases were greatest in the smaller cities. Although cities over 500,000 showed a 17 per cent fatality drop for the first eleven months, the next group of cities, from 250,000 to 500,000 population, showed death reduction averaging only 5 per cent. Toledo, Ohio, continued to lead the death reduction list for large cities with a 46 per cent drop for the first eleven months. Columbus, Ohio, was second with a 41 per cent reduction. Los Angeles and Atlanta, Ga., were in third and fourth places with 37 and 36 per cent drops.

Deaths in Other Countries

Sir William Arbuthnot Lane, consulting surgeon to Guy's Hospital and to the Hospital for Sick Children, London, died in London on January 16, aged 87. He was born in Fort George, Scotland, in 1856 and was educated at St. Andrew's House, Bridge of Allan, and Guy's Hospital Medical School. He had written numerous articles on surgery and anatomy and books on the operative treatment of fractures and cleft palate. Sir William visited the United States in 1925.

Civilian Casualties Sustained in Eleven Months of Air Raids

A book published by the Ministry of Home Security tells the story of the heavy air raids on this country for the eleven months that began in the middle of June 1940, when, unlike the present, we had no adequate defenses and millions of men, women and children found themselves in the front line of the war. In the previous great war 300 tons of bombs were dropped on Britain and killed 1,400 persons. In the present war about 36,000 high explosive bombs weighing about 6,600 tons, together with thousands of incendiaries, were dropped in three months on the London region alone and 12,696 civilians were killed. In one night, May 10, 1941, 1,436 persons were killed in London. Up to the end of 1941 some 190,000 high explosive bombs were dropped on Britain as a whole, and they killed 43,667 civilians, including 5,460 children. Added to this loss of life there were injuries to thousands, and still greater numbers lost their homes.

What was intended to be a knockout blow to London opened on a fine Saturday afternoon, Sept 7, 1940, when 375 bombers and fighters attacked Woolwich Arsenal and the gas works at Beckton and set docks ablaze. After a break of two hours came a procession of 250 night bombers, guided straight to its target by huge riverside fires. When the big raids began, four fifths of London's auxiliary firemen had never seen a fire. They now had a concentrated experience without parallel in years of peacetime fire fighting. At Woolwich Arsenal men fought the flames in the midst of boxes of live ammunition and crates of nitroglycerin. London was bombed for fifty-seven nights without a break, and then the enemy widened the front to include the arms towns and the ports. First there was the vicious raid on Coventry on Nov 14, 1940, about which the Germans boasted as something new in the annals of war. The provincial towns shared this special ordeal of the bombardment in a more concentrated form than London, as much smaller spaces were attacked. Merseyside was Hitler's "target number one" outside London. Here many concentrated attacks were made, including one on seven consecutive nights. Today air attacks on this country are so small and so few that already we are beginning to forget what one is like.

The New Regulation for Compulsory Treatment of Venereal Disease

The new regulation making the treatment of venereal disease compulsory in certain cases was described in a previous letter to THE JOURNAL. In a debate in the House of Lords Lord Winster said that more than 70,000 new infections occurred in 1941 and that syphilis had increased 50 per cent in the civilian population. If the fighting services were added the increase would be in the neighborhood of 70 per cent. The position was rendered more serious by the presence in this country of large numbers of service men and women from abroad. There had been complaints among the chiefs of these forces, particularly as to London.

Viscount Dawson of Penn, himself a physician, said that owing to the wartime increase in venereal disease we were back in the same position as in 1932. The women likely to contract the disease belonged to more classes than was formerly the case. In a crowded country such as this we should lose more than we gained by compulsory notification. One woman was known to give syphilis to seven men in the forces in succession, three of them were married and infected their wives. It was

the hard core of irresponsible women who must be dealt with. The new regulation making treatment compulsory for any person found to have infected two others was the best under the circumstances.

The bishop of Norwich said that opposition to the new regulation was widespread among people who understood the social aspects of the problem. The anonymous informer was alien to this country. There was a danger that an increase of venereal disease would result from the regulation. There should be more treatment centers. More should be done to appeal for self control as the only way of escape, and there should be a nationwide campaign to instruct young people in the danger of promiscuous relationships.

For the government Lord Snell said that its policy was to control and, if possible, to destroy venereal disease. Before the war it had been reduced, but during the war there had been an increase of 70 per cent, including the forces. We had in Great Britain 249 treatment clinics, of which 18 had been opened since the war began. Five more would shortly be opened. A new scheme had been started in rural areas for providing free treatment under special physicians. The new regulation had been carefully framed to provide equality of treatment for men and women. The tracing of persons who spread infection was not a new practice, for most clinics tried to ascertain the source of infection. Every precaution was taken against the dangers suggested. There were heavy penalties for false information. He would be afraid to trust himself to speak about the injury done by self righteous pharisees in regard to this matter. If these diseases were hidden it was because those who contracted them were afraid to be considered social outcasts. They thrived in the conditions of secrecy which had existed for many years. The community should take every step to reduce them. It should be the duty of the individual to refrain from contracting such diseases, or, if he did contract them, to get himself cured as soon as possible.

Treatment of Bacillary Dysentery with Sulfaguanidine

At a meeting of the Royal Society of Tropical Medicine Col N Hamilton Fairley FRS, presented on behalf of himself and Col J S K Boyd the results of work done in the Middle East on the diagnosis and treatment of bacillary dysentery. The disease was mild even with Shiga dysentery the mortality was lower than was expected. But, as the stay in the hospital averaged three to four weeks the waste of manpower was great. Fly transmission was the rule. In the forward areas all exposed excreta and animal carcasses were burned or promptly treated with insecticides. Where possible trench latrines were immediately dug and provided with fly proof covers if available. Failing this, earth was immediately used to cover the stools, which were sprinkled with powdered borax or some insecticide. Shiga dysentery accounted for 10 per cent of the cases.

From a military point of view any one who had colicky pain followed by febrile diarrhea with stools containing flakes of mucus or mucus and blood should be regarded as having dysentery and should be sent away without delay. In the majority of cases ultimate recovery occurred under rest, copious fluids and magnesium sulfate. In milder infections milk drinks could be allowed at a relatively early stage. Serum treatment proved disappointing. It relieved toxic features, presumably by neutralizing circulating toxins, but the benefit was rarely more than temporary.

SULFAGUANIDINE TREATMENT

Two of the first patients treated with sulfaguanidine had received other treatment for three months but none had made any real difference to the ulcers. Within fourteen days of beginning sulfaguanidine treatment the ulcers completely healed and the symptoms disappeared. In a third case of six months' dura-

tion complete healing took place in a fortnight. A much wider investigation was then undertaken in a series of over 500 cases. Care was taken to combat dehydration when present. Administration of sulfaguanidine was followed in some cases by headache or nausea and in a few cases by rash and fever. In 135 proved cases of Shiga dysentery in which recovery occurred under sulfaguanidine, there was usually early astonishing improvement. In 32 cases with an interval from the onset to the beginning of treatment of six to ten days there was an average of 217 stools in the twenty-four hours. The number of stools fell to four in three to five days and to two or less in 54 days. The stools became formed in an average of 715 days. These results were held to indicate an active bacteriostatic effect on the dysentery organism in the bowel wall. Of 12 more chronic cases complete cure was obtained in 9, as shown by sigmoidoscopy. In 2 some diarrhea persisted and there was evidence of sluggish healing.

Precaution Against Dangerous Radiation

Some workers in X-ray departments have fears as to the possible effect on their health of the radiation to which they are exposed. The minister of health has therefore issued a circular letter to hospital authorities on the subject. He is advised that in a well-run department where proper precautions are taken the risk to health is small. But he feels that it would be useful to hospitals and would allay groundless apprehension if they had at their disposal a service for the regular measurement of the radiation received by workers in X-ray departments, so that any excessive or dangerous radiation may be discovered and dealt with. He accordingly approached the National Physical Laboratory on the matter. The laboratory has agreed to organize a service for testing the amount of radiation received by the workers, and to advise what action should be taken. The service is designed primarily for diagnostic workers but can be used for therapy workers. It is available to workers in clinics or for private physicians as well as for those employed in hospitals.

The initial test, which should suffice in the majority of cases, consists in the worker carrying a dental film in the breast or waistcoat pocket. These films will be issued and examined by the laboratory and a report on the amount of radiation received by each worker will be sent to the hospital authority. Should the film test show a dose approaching or exceeding the tolerance value laid down by the British X-Ray and Radium Protection Committee, the hospital should arrange for the testing of the X-ray equipment by ionization methods, and for investigation of the workers' technique. These tests may be made by a physicist attached to the hospital, but, if desired, the laboratory will undertake the investigation and advise on the matter. The dental film test should be repeated at regular intervals of three months.

The minister of health advises hospital authorities and others concerned to make the fullest use of the National Physical Laboratory. Although the risks in a well-conducted laboratory should be small, X-ray tubes may not under war circumstances reach the high standards of peace time. The laboratory makes the small charge of half a dollar for reporting on each film. Where use is made of the laboratory by the emergency hospital scheme (established for the treatment of civilians injured in air attacks) the minister states that the fees paid will be a proper item for including in the running costs of the hospital in the periodic statement of expenditure.

Pensions for War Injuries

The government has adopted a new scale of pensions for war injuries. The 100 per cent disability pension is \$9 a week apart from family allowances and rank additions. The loss of one eye is now assessed at 40 per cent, compared with 50 in the last war, amputation below the knee with a stump exceed-

ing 4 inches has undergone the same change. Loss of both hands or arms, 100 per cent, amputation at or below the shoulder, 50 to 80 per cent, loss of thumb 30 per cent, four fingers, 40 per cent, three fingers, 30 per cent, with reduction of 10 per cent if on the left hand, two fingers, 20 per cent. Double amputation of legs, 100 per cent, both feet, 80 per cent, one foot 30 per cent, amputation at or below the hip, 40 to 80 per cent, loss of all toes on both feet, 20 to 30 per cent, loss of one eye (the other normal), 40 per cent, loss of vision of one eye (the other normal), 30 per cent, loss of a hand and a foot 100 per cent, severe facial disfigurement, 100 per cent. Total deafness 100 per cent, as compared with 70 in the last war.

Medical Aid from South Africa for Russia

It is announced from Johannesburg that 10,000 doses of anti-gas gangrene serum and 2,000 doses of antibacterial dysentery serum are to be sent from the South African Institute of Medical Research to Moscow by air at the urgent request of the Soviet government. It is planned to dispatch a similar consignment each month at a cost to the Medical Aid to Russia Fund of about \$24,000. Later between 30,000 and 40,000 doses of antityphus vaccines will also be sent each month at a cost of between \$6,000 and \$8,000. It is estimated that thousands of Russian lives will be saved by the timely administration of the serums, which should reach the Russian fronts within ten days or a fortnight of leaving South Africa.

Cod Liver Oil and Fruit Juices for Young Children and Expectant Mothers

Under the rationing system of the war, the government entirely controls our food supply. Great attention has been paid to the supply of vitamins, such as cod liver oil and fruit juices for young children and expectant mothers. But the minister of health regrets that only a comparatively small percentage of children eligible are now being given the benefit of these special preparations. With the minister of food he will undertake an extensive publicity campaign to impress on mothers their value, particularly during the winter months. It is recognized that not all women can take cod liver oil, but those who can should be encouraged to do so.

Anglo-Soviet Medical Collaboration

The Anglo-Soviet Medical Council was formed soon after the attack of Germany on Russia to promote medical collaboration between Britain and Russia. It provides translations of the articles which have appeared in one country for publication in the other. A team of thirty-five translators have recently completed the translation into Russian of *Reviews of British War Medicine*. The book was formally presented to Mme Muska, wife of the Russian ambassador, by Sir Alfred Webb-Johnson, president of the council and also of the Royal College of Surgeons. Three thousand copies of volume 1 have gone to Russia, and volume 2, which deals mainly with thoracic surgery, has gone to press.

Government Inaugurates Scheme for Cleaner Milk

As a first step toward a cleaner milk supply, laboratory equipment for testing has been installed at more than a thousand large depots where milk is received. Arrangements for training testers, mainly young women, as the scheme develops are being made. It is hoped that one result will be great reduction in the waste through souring next summer. Other openings in the milk industry are forecast in the decision to set up a national milk recording scheme. This will provide for monthly weighings of each cow's milk. Production will then influence rationing allowances. The scheme is also intended to help in the breeding of high milk production stock.

Production will then influence rationing allowances. The scheme is also intended to help in the breeding of high milk production stock.

BRAZIL

(From Our Regular Correspondent)

Nov. 12, 1942

Pollen Allergy

The problem of pollen allergy is a new one in Brazil. Dr. Ernesto Mendes of São Paulo in a recent paper says that allergic conditions with such a seasonal character that one could assume the pollen to be their cause are not found in Brazil. His conclusions were reached after the examination of 124 patients, 63 per cent of whom had bronchial asthma and 37 per cent had perennial rhinitis. He used one hundred extracts and among these twenty were made with pollens from plants of the city of São Paulo and its vicinity. Of the total number of patients 10.5 per cent showed slight cutaneous reactions to the pollen extracts, but among those who were subjected to allergic rhinitis the positive reactions to pollen reached the higher rate of 13 per cent. Nearly all the patients reacted to more than one extract. The plants that elicited more reactions were those of the species *Eucalyptus globulus* (32 per cent), *Amarantus* sp. (16 per cent), *Chenopodium ambrosioides* (16 per cent) and *Ambrosia polystachia* (16 per cent). Cutaneous reactions to pollen alone were not observed and many positive cutaneous reactions to pollen extracts should be regarded as nonspecific, since the passive transfer test which was performed in 9 cases, gave positive results in only 2. The findings apparently demonstrate that pollen allergy is exceptional in the particular subtropical area referred to and it can be detected only through allergy tests as no clinical symptoms are observed. The extremely low incidence of pollen allergy in Brazil is due to the environment rather than to the individual peculiarities as the potent allergenic plants are few in this country, and the meteorologic conditions do not favor high concentrations of the pollens in the air, particularly in the region of the city of São Paulo. The pollens which reach in the atmosphere of São Paulo sufficiently high concentration to produce pollen allergy are of doubtful allergenic action (*Eucalyptus* and *Parthenium hysterophorus*, between November and February and *Meliss minutiflora* in June and July). The pollens of potent allergenic plants were found in number lower than 15 per cubic centimeter (*Cynodon dactylon* in January and February, *Ambrosia polystachia* from December to March and *Amarantus* from January to April). Some interesting clinical facts have also to be recalled, as for example people who suffer from pollinosis in other countries are relieved by moving to Brazil.

Wild Fire (*Pemphigus foliaceus*)

For the past few years an ever increasing number of cases of a malignant type of pemphigus foliaceus has been reported mainly in the rural areas of the state of São Paulo but also in the central states of Mato Grosso, Minas Geraes, Bahia and Goiás and in the neighboring regions of Paraguay and Bolivia as well. Although the clinical symptoms of pemphigus foliaceus in Brazil are the same as found elsewhere, the itching, burning and acute pain are much more severe and have given rise to the popular name of 'fogo selvagem' (wild fire). In São Paulo alone there are now about 700 cases of the disease. The classic writers stated that the disease was neither epidemic nor contagious, and some of them have ignored the existence of its peculiar manifestations concerned with the tropics, the condition being attributed to toxins, to neuropathic influences, to *Bacillus pyocyaneus* and the like. Dermatologists apparently agree that, whatever its origin, the disease is rare. But the Brazilian experience of recent years contradicts many of these views. The problem became so acute that the state of São Paulo created a special service against the disease, provided with a special hospital of 100 beds and the federal government is building three more of them. It is now proved that the condition is not trans-

missible by direct contact. Well and sick people live in close association during a considerable period of time, and new cases do not arise. The rural areas that constitute the foci are well defined. Suddenly the disease appears in a new area, without any apparent connection with the former. In the large cities there are no autochthonous cases but only those that come to the hospitals. The incidence is higher among women than among men (in the ratio of 3:2) and also higher among people of poor social and economic conditions. Some authors believe in a food deficiency cause, but the poorer zones of the state of São Paulo (the littoral and the northern zones, for instance) are clearly spared. All the lowlands are also free from the disease. The characteristic elementary lesion is a serous purulent bulla on the face, chest and legs, and then the eruption tends to generalize. It must be distinguished from Duhring's dermatitis (which has a different localization with a good general health), from subacute Brocq's type of pemphigus with extensive bullae, from the true acute infectious pemphigus and from bullous impetigo. Once initiated wild fire may develop into one of four types: acute, subacute (most common), superacute (generally fatal after a short period of illness) or chronic. In the chronic cases nails take a yellowish tint as if dipped in iodine (Vulcan sign). In most cases itching is a predominant symptom but a warm burning sensation is usually commoner.

After failing to find a visible microbial cause of the disease, Lindenbergh of São Paulo decided that in view of the obvious infective nature of wild fire a virus must be responsible. He tried the transmission of the disease to rabbits and thinks that he succeeded but J. P. Vieira, an authority on the subject failed to confirm Lindenbergh's results. The low alkali reserve of the blood suggests the necessity of some special diet. The treatment must be begun early with antiseptic baths, quinine by mouth and protection of the skin with a heavy layer of borated petrolatum or else the disease goes on and there is no cure possible. The Brazilian pemphigus foliaceus is a serious problem awaiting particular attention and continuous study.

Marriages

HENRY WILLIAM SCOTT JR., Graham, N. C., to Miss Mary Louise Varnum of Cape Elizabeth, Maine at Portland, Maine October 17.

WILLIAM A. VAN NORTWICK, Greenville, N. C., to Miss Grace C. Taylor in Merchant City, November 7.

ROBERT HENRY CLAVAND to Miss Hannah Elizabeth Iubank both of Jacksonville, Fla. October 10.

MARION LAWRENCE WHITE JR., Reedville, Va., to Miss Emma Cassandra Macon at Orange, November 22.

JAMES LAWRENCE JORDAN JR. to Miss Mary Katherine Boswell, both of Huntsville, Ala. recently.

ILLEN WHITMORE BANE, Prainerd, Minn., to Mr. Henry Longfellow of Beloit, Wis. December 9.

WILLIAM H. WAITERS JR., Lacombe, Fla., to Miss Helen Hancock in Jacksonville in November.

WILLIAM E. MITCHELL, Asheville, N. C., to Miss Margaret John Holland in Detroit, October 17.

PETER JOHN FRIDMAN JR. to Miss Helen Marguerite Cruze, both of Knoxville, Tenn. October 24.

PAUL J. ISERN, Fort Howard, Maryland, to Miss Regina Nelson of New York, December 20.

ABRAHAM BERRY, Columbia, S. C., to Miss Bernice Frances Coleman of Charleston, October 18.

OREN A. ELLINGSON, Brooklyn, to Miss Florence Rosamond Carson at Nashville, Tenn., recently.

JENNINGS KERR OWENS, Bennettsville, S. C., to Miss Grace S. Buie of Denmark, November 28.

JAMES J. O'HALLORAN, Moline, Ill., to Miss Camille Nolan of Davenport, Iowa, November 26.

HUBERT CLAYTON JR., Hopkins, S. C., to Miss Florence Rivers Armour at Eastover, October 18.

Deaths

Howard Atwood Kelly * world famed as a pioneer in gynecology, died at the Union Memorial Hospital, Baltimore, January 12, aged 84, of generalized arteriosclerosis and uremia. His death preceded by a few hours that of his wife, who lay ill in an adjoining room.

Dr Kelly was born in Camden, N J, Feb 20, 1858, he received his bachelor of arts degree at the University of Pennsylvania Philadelphia in 1877 and his medical degree at the same university in 1882. While a resident physician in the Episcopal Hospital, Dr Kelly developed a gynecologic dispensary clinic. On completion of his internship he established a two room hospital, which later became the Kensington Hospital, to be supported by voluntary contributions. He was called from his position as associate professor of gynecology at the Pennsylvania Department of Medicine to become the first professor of gynecology and obstetrics at Johns Hopkins University and obstetrician in chief to the Johns Hopkins Hospital Baltimore. In these early days Dr Kelly's hospital work was limited to gynecology. The opening of the medical school in 1893 and the need for obstetric facilities were responsible for the separation in 1899 of the department of obstetrics and gynecology into two divisions. From then on Dr Kelly concentrated all his efforts on the development of gynecology. He had been emeritus professor of gynecology at the medical school since 1919 and consulting gynecologist to the hospital since the same year. In 1892 he was responsible for the establishment of the sanatorium which bore his name. In 1913 the institution which closed in 1938 became the Howard A. Kelly Hospital. Here he served at various times as radiologist and surgeon physician in chief and superintendent.

Throughout the years, Dr Kelly showed himself to be a pioneer in numerous forms of medical study. He was one of the first to use cocaine for local anesthesia. His work in abdominal surgery was revolutionary and his early interest in cancer and radiation resulted in many brilliant contributions. He is the inventor of the Kelly pad, rectal and vesical speculums and an operative technic which bears his name. In 1933 at a special assembly to honor him on his seventy fifth birthday, Dr Kelly was credited by Max Brodel with the successful development of medical illustration as a specialty.

During his career many honors were bestowed on him. He was an honorary member and fellow of numerous scientific societies, including the Chicago Gynecological Society, American Urological Association, Seaboard Medical Association, Virginia and North Carolina medical societies, American Radium Society, American Association for the Advancement of Science, American Geographic Society, Maryland Academy of Sciences, of which he was a life member, Natural History Society of Maryland, Philadelphia Academy of Natural Sciences, New York Zoological Society, New York Botanical Gardens, American Museum of Natural History and American Society of Ichthyologists and Herpetologists. In addition, Dr Kelly held honorary memberships in many European groups. He was president of the Southern Surgical and Gynecological Society in 1907 and of the American Gynecological Society in 1912. He was secretary of the Section on Obstetrics and Diseases of Women of the American Medical Association from 1890 to 1891 and a founder member of the American College of Surgeons in 1913. In 1928 he gave the Hunterian Lecture in the Mansion of the Lord Mayor of London. The occasion marked the two hundredth anniversary of the birth of John Hunter.

Dr Kelly wrote extensively on a variety of subjects. His works include *Operative Gynecology* (two volumes, 1898, 1906),

Vermiform Appendix and Its Diseases (with Elizabeth Hurdon), 1905, *Walter Reed and Yellow Fever* 1906, 1907 and 1923, *Gynecology and Abdominal Surgery* edited with C P Noble volume 1, 1907, volume 2 1908. *The Stereo Clinic* (eighty-four sections), 1908- *Medical Gynecology*, 1908 and 1912. *Appendicitis and Other Diseases of the Vermiform Appendix* 1909. *Myomata of the Uterus* (with T S Cullen) 1909. *Cyclopedia of the American Medical Biography*, two volumes, 1912. *Some American Medical Botanists* 1913. *Diseases of the Kidneys, Ureters and Bladder* (with C F Burnham two volumes), 1914 and 1922. *American Medical Biographies* (with W L Burrage), 1920. *A Scientific Man and the Bible* 1925, *Gynecology* 1926. *Dictionary of American Medical Biography* (with W L Burrage), 1928, *Electrosurgery* (with Grant E Ward), 1932.

Frequently referred to as the father of gynecology, Dr Kelly is the last of the memorable four of medicine represented in Sargent's famous portrait of Osler, Halsted and Welch.

Dr Kelly was a man of broad interests and great enthusiasms. His active mind, his arresting personality and his extraordinary skill attracted to him students from all over the world. His intellectual curiosity in many fields apart from medicine kept him in the forefront of public interest.

Besides gynecology and surgery he was competent in the fields of botany, natural history and anthropology and he did not hesitate to express himself regarding politics and religion. His religious beliefs inclined toward fundamentalism and he was at the time of his death a member of the board of the William Jennings Bryan University at Dayton Tenn. He was also an ardent advocate of prohibition of alcoholic liquors and of strict observation of the Sabbath. In behalf of these interests he spoke and wrote frequently. He had been in his youth a champion swimmer, a competent cowboy and an expert canoeist and his knowledge of poisonous snakes made him a recognized authority in that field. His friends and correspondents were legion. Even those with whom he debated fiercely and at length honored him for his intellectual integrity.

Aaron Joshua Rosanoff * Beverly Hills Calif. Cornell University Medical College, New York, 1900, director of state institutions from 1939 to 1942, for many years a member of the Los Angeles County Lunacy Commission, member of the American Psychiatric Association, a charter member, board member and past president of the Southern California Academy of Criminology.

a charter member, board member and past president of the Southern California Society for Mental Hygiene, at one time professor of medicine (psychiatry), College of Medical Evangelists, Los Angeles, lecturer in psychiatry at Columbia University, New York, from 1919 to 1921 and formerly at the University of Southern California, Los Angeles, during World War I served in the neuropsychiatric service of the U S Army, treating victims of shell shock and similar injuries. For his work in this field was the recipient of a special citation from the government, a captain and major in the medical corps of the U S Army from 1917 to 1919 and a lieutenant colonel in the medical reserve corps from 1920 to 1930, organized and founded the Langley Porter Clinic, San Francisco, specialist certified by the American Board of Psychiatry and Neurology, Inc., junior assistant physician at the Kings Park (N Y) State Hospital from 1902 to 1905, assistant physician from 1905 to 1908, senior assistant physician from 1908 to 1911 and clinical director from 1911 to 1922, owner and medical director of the Alhambra Sanatorium, Rosemead, consulting psychiatrist to the Kaspary Cohn Hospital, Los Angeles, from 1923 to 1928, co-author of 'Etiology of Mental Deficiency with Special Reference to Its Occurrence in Twins,' psychologic monographs published in 1937, author of 'Manual of Psychiatry and Mental Hygiene,' seventh edition published in 1938, an associate editor of the *American Journal of Psychiatry*, aged 64, died January 7, of carcinoma of the lungs.

HOWARD ATWOOD KELLY, M D, 1858 1943

A Noah Schiller ⊕ New York, Columbia University College of Physicians and Surgeons, New York, 1907, member of the American Academy of Ophthalmology and Otolaryngology, one of the founders of the Jewish Memorial Hospital, where he was honorary chairman and chairman of the medical board, consulting otolaryngologist and for many years chief of the department of otolaryngology, consulting otologist and attending physician in the ear, nose and throat division of the New York City Hospital, Welfare Island, aged 58, died, December 17, in Miami Beach, Fla., of coronary occlusion.

Seavy Highsmith ⊕ Fayetteville, N. C., University College of Medicine, Richmond, 1901, member of the Southern Medical Association, past president of the Cumberland County Medical Society, member and in 1939 president of the Fifth District Medical Society, member and past vice president of the Tri-State Medical Society, vice president of the North Carolina League for Crippled Children, aged 68, co owner and secretary of the Cumberland General Hospital from 1917 to 1927, from 1905 to 1917 on the staff of the Highsmith Hospital, where he died, December 8, of heart disease.

John Mitchel Johnson Jr., San Sabá, Texas, Tulane University of Louisiana School of Medicine, New Orleans 1936, practiced at Longview, where he served on the staff of the Van Sickel Clinic-Hospital, aged 31, was commissioned a lieutenant, junior grade, in the medical corps of the U. S. Naval Reserve and began active duty in March 1942, had recently been promoted to lieutenant senior grade, was killed in action recently somewhere in the Pacific.

James Gordon Henderson, Beverly Hills, Calif., Stanford University School of Medicine, San Francisco, 1925, formerly assistant clinical professor of surgery (genitourinary) at his alma mater, member of the American Urological Association, resident physician, St. Francis Hospital, 1925-1926, resident in urology at the Stanford University Hospital from 1926 to 1928, visiting urologist, Laguna Honda Home, from 1928 to 1931, assistant visiting urologist at the San Francisco Hospital for many years, urologist San Francisco Polyclinic, from 1929 to 1935, aged 44, died in November.

Charles Blanchard Bard, Water Valley, Ky., University of Louisville Medical Department 1912, member of the Kentucky State Medical Association, served overseas during World War I, aged 54, died, December 3, at the Mayfield (Ky.) Hospital of coronary heart disease.

L. Ernest Belanger, Montreal, Que., Canada, M.B., School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal in 1907, and M.D. in 1909, aged 60, died November 12.

Edward J. Broderick, St. John, N. B., Canada, McGill University Faculty of Medicine, Montreal, Que., 1890, aged 76, died, December 1.

Eugene Carmichael, Cedar Rapids, Iowa, State University of Iowa College of Homeopathic Medicine, Iowa City, 1900, aged 74, died, November 29, of angina pectoris.

George Bradford Curry, Bolivar, Tenn., Memphis Hospital Medical College, 1903, aged 66, died, November 28, in the Baptist Memorial Hospital, Memphis, of intestinal obstruction.

Albert Downing, Carleton Place, Ont., Canada, University of Toronto Faculty of Medicine, 1895, for a number of years served as a member of the board of education and as deputy reeve, medical officer of health for Carleton Place, appointed a coroner for the county of Lanark while practicing at McDonald's Corners and continued to serve in that capacity during his residence in Carleton Place, aged 68, died, October 16.

Rufus Cecil Franklin ⊕ Swainsboro, Ga., University of Maryland School of Medicine, Baltimore, 1907, member of the Southeastern Surgical Congress, president and secretary of the Emanuel County Medical Society, had been a member of the city council and chairman of the local school board, director of the Citizens' Bank, medical superintendent and owner of the Franklin Hospital, aged 61, died, December 4, in a hospital at Atlanta of hemiplegia.

Albert Lincoln French, Lincoln, Neb., Medical School of Maine Portland, 1882, aged 82, died, December 3, in St. Elizabeth Hospital of carcinoma of the liver.

Ralph Winward French ⊕ Fall River, Mass., Harvard Medical School, Boston, 1910, specialist certified by the American Board of Surgery, member of the New England Surgical Society, fellow of the American College of Surgeons, aged 59, was instrumental in establishing a training school for nurses and a member of the surgical staff of the Truesdale Hospital, where he died, December 7, of a spontaneous subarachnoid hemorrhage.

John Phillip Gibbs ⊕ Chicago, Harvey Medical College, Chicago, 1905, for many years on the staff of St. Elizabeth Hospital, aged 79, died, December 5, in Spring Grove, Ill., of arteriosclerosis.

Lindon Lemuel Gillett, Suffern, N. Y., University of Wooster Medical Department, Cleveland, 1887, aged 77, died, November 8, in the Hackensack (N. J.) Hospital of diabetes mellitus and a fracture of the femur resulting from a fall.

Charles Judson Gordon, Sicily Island, La., Kentucky School of Medicine, Louisville, 1898, member of the Louisiana State Medical Society, aged 69, died, December 4, of heart disease.

Richard H. Greenwell, Bardstown, Ky., Hospital College of Medicine, Louisville, 1906, member of the Kentucky State Medical Association, secretary of the Nelson County Medical Society, health officer of Nelson County, aged 64, died, December 6.

James Richard Greer, Danville, Ill., Rush Medical College, Chicago, 1912, formerly assistant clinical professor of medicine at his alma mater, member of the medical staff of the Presbyterian Hospital, Chicago, from 1913 to 1929, aged 66, died, December 1, of recent dilatation of the heart following chronic myocardial degeneration.

J. L. Griffin, Vandalia, Ark., Memphis (Tenn.) Hospital Medical College, 1903, member of the Arkansas Medical Society, aged 67, died, December 2.

Emery Fremont Griffith, Peru, Iowa, College of Physicians and Surgeons, Keokuk, 1887, aged 81, died, November 9, of cerebral hemorrhage.

Edward Cleveland Hagler, Tuscaloosa, Ala., Medical College of Alabama, Mobile, 1904, member of the Medical Association of the State of Alabama, served in the medical corps of the U. S. Army during World War I, aged 63, died, December 4.

Joseph W. Halford, Raleigh, N. C., George Washington University School of Medicine, Washington, D. C., 1904, was vice president of the bank of Lillington, had served as chairman of the county board of commissioners and as mayor of Lillington, aged 72, died, November 28, in Lillington of burns received when he fell asleep while smoking.

William Heston Harper ⊕ Columbus, Ohio, Ohio Medical University, Columbus, 1901, aged 69, died, December 6.

Gray Godwin Holladay, Portsmouth, Va., Bellevue Hospital Medical College, New York, 1893, fellow of the American College of Surgeons, served in the U. S. Navy during World War I, in 1917 was senior medical officer of the transport *George Washington*, which brought the King and Queen of Belgium to the United States, was decorated by the King with the Belgian Order of Leopold for many years surgeon for the Seaboard Air Line Railway, and city coroner of Portsmouth, aged 72, died, November 26, in the King's Daughters' Hospital of chronic myocarditis and carcinoma of the jaw.

Walter B. Holmes, Wadley, Ga., Baltimore Medical College, 1892, member of the Medical Association of Georgia, aged 72, died recently.

John H. Horne, Robeson, Pa., Jefferson Medical College of Philadelphia, 1891, member of the Medical Society of the State of Pennsylvania, aged 77, died, November 14.

Edwin Everett Jack, Brookline, Mass., Harvard Medical School, Boston, 1887, member of the Massachusetts Medical Society, the American Ophthalmological Society, the Association for Research in Ophthalmology, Inc., and the New England Ophthalmological Society, specialist certified by the American Board of Ophthalmology, consultant, Children's Hospital Boston, from 1895 to 1918, member of the consulting staff, Massachusetts Eye and Ear Infirmary, Boston, aged 79, died, November 16, of angina pectoris.

KILLED IN ACTION

LIEUT. JOHN MITCHEL JOHNSON JR.,
M. C., U. S. N. R., 1911-1942

Leo Harold Joyce @ Passaic N J , Baltimore Medical College, 1902, was president of the Passaic County Maternal Welfare Association, aged 64, formerly chief of staff of St Mary's Hospital where he died December 7

Maurice Kahn @ Chicago Baltimore University School of Medicine, 1903, on the staff of the Evangelical Hospital aged 66, died, December 8, in the Albert Merritt Billings Hospital of carcinomatosis

Enos E Kincheloe, Church Hill, Tenn University of Tennessee Medical Department Nashville, 1891, aged 79 died, November 5

August E Kipp, Cincinnati Cincinnati College of Medicine and Surgery, 1890, aged 93 died, November 12, of intestinal obstruction and peritonitis

William Sherman Lessenger, Mount Pleasant, Iowa, State University of Iowa College of Medicine, Iowa City, 1890 member of the Iowa State Medical Society, aged 74, died November 28

Samuel Stockton Miles, Baltimore Johns Hopkins University School of Medicine, Baltimore 1940 had been medical resident to the City Hospital, Winston-Salem, N C since July 1, 1941, commissioned a lieutenant (j g) in the medical corps of the U S Naval Reserve in May 1942, attached to the Marine Corps, aged 28, was killed in action at Tulagi on the Florida Island in the Solomons, August 7

George Samuel Laird @ Westfield N J , University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901 served as a lieutenant in the medical corps of the U S Army during World War I, recently chief of the medical staff of the Selective Service Board number 4, for many years member of the board of health and chief medical inspector for the school system, director of the First National Bank, aged 65, on the staff of the Children's Country Home and the Elizabeth (N J) General Hospital, where he died, December 1

Ardashes H Merdinyan, Pawtucket, R I Medico Chirurgical College of Philadelphia 1905 member of the Rhode Island Medical Society, past president and secretary of the Pawtucket Medical Association medical examiner for the local board, division number 1, during World War I served as medical inspector of the schools of Central Falls, aged 65 died November 26 of coronary thrombosis

Edward Sanford Montgomery, Santa Cruz, Calif Rush Medical College, Chicago, 1894 aged 70, died, November 29

Edith Taft Morehouse, Westfield, N J Woman's Medical College of Pennsylvania, Philadelphia 1913, in 1918 went to France with the American Woman's Hospital of the American Red Cross to engage in rehabilitation work among children in areas devastated by World War I, at one time appointed by the foreign missionary society of the Methodist Church as superintendent of a hospital at Kolar, South India aged 68 died December 13 in the Muhlenberg Hospital Plainfield, of Parkinson's disease

Joseph D Morgan, Dixon, Ohio Georgia Eclectic Medical College, Atlanta 1881, served as state senator for two terms aged 85 died December 11, of senility

Andrew B Nelles, Blacklick Ohio, University of Michigan Homeopathic Medical School, Ann Arbor, 1890 for many years on the staff of the Children's Hospital, Columbus aged 73, died, November 23, of pneumonia

John S Nelson, Fort Dodge Iowa State University of Iowa College of Homeopathic Medicine, Iowa City 1888, aged 82, died November 12 of cardiorenal vascular disease

George Harvey Parmenter @ St Petersburg Fla , University of Vermont College of Medicine, Burlington 1902, member of the Vermont State Medical Society, at one time chief of the medical staff of the U S Veterans hospitals in Des Moines and Fort Harrison, Mont aged 66 died, November 27, in Veterans Administration Facility, Bay Pines, of arteriosclerosis and myocardial failure

Arthur Madison Phillips, New York University of Buffalo School of Medicine 1902 member of the Medical

Society of the State of New York and the American Psychiatric Association instructor of psychiatry at the Cornell University Medical College, assistant superintendent of the Manhattan State Hospital Ward's Island where he began active duty in 1904, aged 64 died, December 16 in the New York Hospital of aneurysm of a ruptured abdominal aorta

Isaac William Powell, Bellingham Wash Kentucky School of Medicine, Louisville 1894 formerly health officer of Bellingham at one time acting assistant surgeon in the U S Public Health Service served during World War I aged 68, died, November 17

James Daniel Renick, Smiths Grove Ky Vanderbilt University School of Medicine, Nashville, Tenn 1880 aged 86 died November 28

James C Rush, Waynesboro, Miss University of Louisville (Ky) Medical Department, 1892 aged 75 died November 23 in the Rush's Infirmary, Meridian of sarcoma of the prostate and angina pectoris

Harry Johnson Schott, Los Angeles Rush Medical College Chicago 1911 member of the American Academy of Orthopaedic Surgeons fellow of the American College of Surgeons specialist certified by the American Board of Orthopaedic Surgery Inc served during World War I chief orthopedic consultant to the city schools aged 55 on the staffs of the Orthopaedic Hospital and St Vincent's Hospital where he died November 24 of an intracapsular fracture of the right femur due to a fall and pulmonary embolism

James F Simkins, Circleville Ohio, Western Pennsylvania Medical College, Pittsburgh, 1891, aged 83 died, November 27

Walter E Storm, Wilmington, N C , New York Homeopathic Medical College, New York, 1877 member of the Medical Society of the State of North Carolina, aged 87, died November 12

Ernest Hamilton Streit, Portland Ore Jefferson Medical College of Philadelphia, 1912 served during World War I, aged 56, died, November 6

Hal Shackelford Tucker, Laurel, Miss , Medical Department of Tulane University of Louisiana, New Orleans, 1887, aged 88, died December 1

Edwin Hugh Van Patten, Dryton, Wash Rush Medical College, Chicago, 1883 aged 87 died, November 28

Robert Reynolds Vogt, Cleveland, University of Wooster Medical Department Cleveland, 1894 aged 70, died, November 8 of cerebral hemorrhage

Edward Everett Watts, Gifford, Idaho, Eclectic Medical Institute Cincinnati 1892, aged 88 died November 14, in St Joseph's Hospital, Lewiston of myocarditis

John Horace Wrork @ Shelburn Ind , Illinois Medical College Chicago, 1904, president of the Sullivan County Medical Society for many years member of the Sullivan County Council, aged 72, died, December 1, in the Mary Sherman Memorial Hospital, Sullivan of cerebral hemorrhage

KILLED IN ACTION

LIEUT SAMUEL STOCKTON MILES,
M C, U S N R, 1913-1942

DIED WHILE IN MILITARY SERVICE

Frederick James Cunningham Smith @ Ardmore Okla , Harvard Medical School, Boston, 1932 a diplomate of the National Board of Medical Examiners commissioned a first lieutenant in the Army of the United States called to active duty Feb 13, 1941, later held the temporary rank of captain aged 35 died, September 9, while in Australia

Leo Paul Martin @ Missoula, Mont Creighton University School of Medicine Omaha 1927 captain in the medical corps of the Army of the United States, died October 25, at Walla Walla Wash where he was station complement flight surgeon, aged 38

Bureau of Investigation

DANGEROUS TO HEALTH

When Used as Directed

[EDITORIAL NOTE—These abstracts differ from other abstracts of Notices of Judgment issued by the Food and Drug Administration of the Federal Security Agency which have appeared in these pages in that they include reference to the fact that these nostrums were specifically declared to be dangerous when used in accordance with the directions given on the label by the manufacturer. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

B D Mint Powders—South Bluefield Pharmacy Inc. Bluefield W. Va. Shipped Oct. 25, 1940. Composition in each powder approximately 343 grains of acetophenetidin, 223 grains of acetaminol, 15 grains of extracted caffeine and 3.6 grains of sodium bicarbonate with unreported amounts of milk sugar, saccharin for sweetening and peppermint oil for flavoring. Adulterated because label falsely claimed that each powder contained not over 2½ grains of acetophenetidin. Misbranded because dangerous to health if used as directed in the labeling also misbranded because claims on display card no harmful ingredients among others and the designation B D Mint were false and misleading since the product contained potentially harmful ingredients was not free from danger might cause serious after effects and the chief active ingredients were not derived from mint. Also misbranded because claims on wrapper that product offered quick relief from pain and discomfort arising from simple head ache, neuralgia, muscular aches and pains and head colds was a nerve sedative and relieved female pain, rheumatism, crache, toothache and fever were false and misleading and likewise was the statement. Prepared by B D Medicine Co. Pataski, Va. since the product had actually been prepared by the South Bluefield Pharmacy, Bluefield, W. Va. Further misbranded because label failed to bear the common or usual name of each active ingredient and a correct statement of the quantity or proportion of acetaminol and acetophenetidin present as well as adequate directions for taking and sufficient warnings against use in those pathological conditions or by children when its employment might be dangerous to health and against use if dosage or methods or duration of administration.—[D D N J F D C 429 September 1942]

Casey's Compound—George E. Madison Company, San Francisco, Calif. Shipped Feb. 12, 1941. Composition a flavored syrup containing 19.8 grains of potassium iodide per fluid ounce. Misbranded because dangerous to health when used in the dosage and with the frequency and duration prescribed suggested and recommended in the labeling, also because label failed to bear adequate directions for taking or sufficient warnings against use in conditions wherein it may be dangerous to health or caution against unsafe dosage or duration of administration. Further misbranded because of false representations in leaflets supplied to customers on request namely that the product is efficacious in relieving arthritis, neuritis, rheumatism and scurvy improving the user's health and enabling him to enjoy a good night's rest.—[D D N J F D C 431 September 1942]

Catawba's Nerve—W. B. Coehel trading as Botanical Medicine Company, Kannapolis, N. C. Shipped between June 7 and 10, 1940. Composition in each ½ fluid ounce not more than 397 grains of sodium bromide, 37 grains of potassium bromide and not less than 0.91 gram of ammonium bromide whereas the respective amounts of these drugs were represented to be 4½, 4½ and ½ gram hence adulterated. Misbranded for the same reason and because product would be dangerous to health when used according to directions on label. Further misbranded because bottle label represented product to be a safe and appropriate treatment for the conditions mentioned thereon (which were not named in the government's abstract of the case) and did not give adequate directions for taking or warn against use by children or in those pathological conditions wherein it might be dangerous to health or caution against unsafe dosage or methods or duration of administration for protection of users.—[D D N J F D C 426 September 1942]

Cold Special No. 2 Red (also called Cold Special Capsules and Capsules Cold Special)—Found offered for sale at Albany Pharmacy, Southern Drug Company and National Press Pharmacy, all located in the District of Columbia. Composition each capsule contained approximately 2 grains of acetaminol and ½ grain of quinine sulfate with unnamed amounts of camphor, podophyllin and aloin. Misbranded because among other things dangerous to health when used in the dosage or with the frequency and duration prescribed in the labeling because labeling failed to give adequate warning against use in those pathological conditions and by children when such use might be dangerous to health or against unsafe dosage or duration of administration for protection of users further because designation

'Cold Special' was false and misleading, since the product did not constitute a treatment or preventive for the condition commonly known as cold.—[D D N J F D C 432 September 1942]

Holomist—Holomist Inc. Seattle, Wash. Shipped between May 27 and June 6, 1941. Composition essentially racemic epinephrine hydrochloride (in one specimen 23 grains in the other, 24 grains per hundred cubic centimeters) chlorobutanol and water. Misbranded because dangerous to health when used in the dosage or with the frequency or duration prescribed in labeling, further misbranded because of false and misleading label claims that it would be efficacious for relieving paroxysms of bronchial asthma, treating hay fever or sinusitis, preventing asthma attacks, building up natural resistance strength and might enable user to eat what he pleased, soothing the membranes acting as an ideal antiseptic for the sinuses, building up resistance against sinus disorders and catarrhal conditions and toughening the tissues against infection and irritation. Also misbranded because carton did not give common or usual names of active ingredients or state quantity or proportion of chlorobutanol present, manufacturer's name and address were not prominently placed on the carton and carton did not bear an accurate statement of the quantity of contents.—[D D N J F D C 433 September 1942]

Happy Day Headache Powders—Shipped Sept. 16, 1940 in part by Alex Caplan, owner of the Capital Drug Company, Roanoke, Va. and in part by the Sessions Specialty Company, manufactured by Gulf Laboratories Inc., Lafayette, La. Composition essentially acetaminol (2½ grains per powder), aspirin, caffeine, phenolphthalein and milk sugar. Misbranded because dangerous to health when used as recommended in the labeling, also because labeling failed to give adequate directions for use and did not contain necessary warnings against employment in those pathological conditions or by children when its use might be dangerous to health, also because of false labeling representations as to its efficacy for relief of discomfort arising from head colds, hay fever, nervousness, menstrual disturbance, tonsillitis, sinus trouble, headache, rheumatism, influenza and throat irritations and because label did not bear the common or usual names of the active ingredient or an accurate statement of their quantity.—[D D N J F D C 444 September 1942]

Hillman's D Compound—David Hillman trading as Hillman Pharmacy, Chicago, Ill. Shipped Feb. 5, 1940. Composition capsules each containing ammoniopyrine (1.44 grain) and a small amount of ephedrine sulfate with milk sugar flavored with peppermint oil. Misbranded because dangerous to health when used in the dosage or with the frequency or duration prescribed recommended or suggested in the labeling because labeling did not bear adequate direction for use or sufficient warnings against unsafe dosage or methods or duration of administration in the manner necessary for the protection of users and because label gave the impression that the product was a safe and appropriate treatment for the conditions mentioned (dysmenorrhea and the cramps, headache and headache which accompany menstruation) whereas it was a dangerous product and the label failed to reveal that its use might cause serious blood disturbances.—[D D N J F D C 427 September 1942]

Samaritan Treatment Preparations—Suppletive Formula Number 1 Supportive Formula SGMa and Formula Number 1—E. S. Miller Laboratories, Inc., Los Angeles Shipped between May 3 and Oct. 17, 1940. Composition Suppletive Formula Number 1—emetine hydrochloride. Supportive Formula SGMa—entirely glandular material and water. Formula Number 1—entirely compounds of ephedrine, pilocarpine, emetine and strychnine with sulfate, chlorides and water. Suppletive Formula Number 1 misbranded because dangerous to health when used in the dosage suggested in the labeling. The product and Formula Number 1 were misbranded because labeling failed to warn adequately against use in those pathological conditions (or by children in the case of Formula Number 1) when their use might be dangerous to health or against unsafe dosage or methods or duration of administration, because necessary for protection of user. All three products misbranded because labeling failed to give adequate directions for use and because they were fabricated from two or more ingredients and labeling failed to give common or usual names of active ingredients.—[D D N J F D C 435 September 1942]

Syn O Scope and Synex—Syn O Scope Laboratories, Los Angeles Shipped Aug. 24, 1940. A device (Syn O Scope) and accompanying liquid (Synex). Composition Synex—essentially 10 per cent of alcohol by volume with camphor, eucalyptus oil and water. Syn O Scope misbranded because dangerous to health when used in dosage which label specified or as label recommended for the application of medicaments to irritated and congested nasal passages, since these and other directions falsely represented that the product was efficacious for the purpose recommended. Device and liquid misbranded in that carton and vial containing the liquid did not bear the common or usual names of the active ingredients, including the quantity of alcohol or the name and address of the manufacturer, packer or distributor.—[D D N J F D C 437 September 1942]

Wondersalve—Brookgate Remedy Company, Evansville, Ind. Shipped Dec. 21, 1939. Composition phenolic compounds including carbolic acid (5.44 per cent), camphor and turpentine in an ointment base. Misbranded because of false and misleading claims on the label that it would be efficacious for all cases of inflammation or infection. For misbranded members cinders or any other foreign substances in the eye further misbranded because dangerous to health when used according to directions in the labeling. Also misbranded under the Federal Cautious Poison Act as reported in Notice of Judgment 103 published under that Act.—[D D N J F D C 438 September 1942]

Pennsylvania July Report

The State Board of Medical Education and Licensure reports the written examination for medical licensure held at Philadelphia and Pittsburgh July 7-9, 1942. The examination covered 5 groups and included 50 questions. An average of 75 per cent was required to pass. Four hundred and thirty-seven candidates were examined. 420 of whom passed and 17 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
College of Medical Evangelists	(1941)	(1942)*	2
Stanford University School of Medicine	(1942)	(1942)	1

Cornell University Medical College		(1937)

* Licensed to practice surgery only

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Sale of Asthmanol by Layman

—An information was filed against the defendant, charging, in part, that he did unlawfully practice the healing art by examining, treating, and prescribing for one Mamie L. Murphy, without having first obtained a license so to do from the Commission on Licensure for the District of Columbia against the form of the statute in such case made and provided, "From a conviction in the police court, where it was conceded that the defendant did not have a license to practice, the defendant appealed to the United States Court of Appeals for the District of Columbia.

For about eighteen years the defendant had been manufacturing an asthma remedy called "asthmanol," which he sold for \$10 a bottle. In connection with the sale of "asthmanol" the defendant made certain recommendations concerning the general health of the purchasers, and when they were suffering acutely from asthma and needed special care the defendant had facilities in his home to render it. The evidence showed that a Mrs. Murphy consulted the defendant and told him that she had asthma and heart trouble. The defendant gave her some little pink pills and she arranged with him to return to his home the next week and to stay for a period of three weeks for treatments. The defendant told Mrs. Murphy that he would cure her and that the price would be \$100. Mrs. Murphy returned at the appointed time and the defendant gave her more pills. She was then put to bed in a rear bedroom, which was occupied by other "patients." She was put on a diet and the defendant gave her pills and "asthmanol" when he thought it necessary. Some of the pills administered by the defendant contained pure salts, cascara and capsicum, and others contained sodium bicar-

bonate. The "asthmanol" consisted largely of whisky and contained also a small amount of gentian. Mrs. Murphy and the other patients all called the defendant "doctor."

The defendant first contended that the information was insufficient because it failed to allege that the defendant practiced "for a fee, gift or reward, or in anticipation of a fee, gift or reward, whether tangible or intangible." The degree of particularity required in the averments of an information, the court said, is that which is necessary to enable the accused to understand the nature of the charge against him, intelligently to meet it and to plead the result, whether conviction or acquittal, as his protection against another prosecution for the same offense. The averments must be sufficient to inform the court of the facts alleged so that it may decide whether they are sufficient in law to support a conviction and that the offense may judicially appear to the court when it pronounces judgment. The court was satisfied that in the present case the information conformed to the rule.

The defendant introduced the testimony of two physicians, referred to in the decision of the court as Dr. Dull and Dr. Butz. One of them stated that he had diagnosed Mrs. Murphy's condition as bronchial asthma and that in his opinion the acts done by the defendant amounted to nothing more than ordinary nursing services and did not constitute the practice of medicine. The other said that Mrs. Murphy was a former patient of his, that he had told her about the defendant and had given her the defendant's address but that she had gone to the defendant's house of her own volition. He, too, testified that in his opinion the things done by the defendant were only the usual functions of a nurse and that it was going too far to say that the defendant was practicing medicine in the ordinary sense of that term.

The defendant argued that the healing arts practice act exempted the manufacture and sale of medicines as well as "nursing" and said that everything done by him beyond the selling of his medicine constituted no more than nursing. He further contended that the act expressly exempted the use of ordinary hygienic, dietetic or domestic remedies and that the remedies which he applied in this case were domestic remedies. It is true said the court, that people frequently administer remedies to themselves in their own homes, it is true that nurses acting under the instruction of doctors, sometimes perform duties which doctors themselves would otherwise perform and which, otherwise, would come clearly within the scope of the practice of medicine. But neither people in the privacy of their own homes nor nurses acting under the instruction of physicians represent to persons who are otherwise strangers to them that they will cure them of disorders for a price specified, as was done in this case. The defendant's activities, the court thought brought him clearly within the proscription of the act. The definition of "the healing art" set out in the act is made up of a series of clauses stated disjunctively. Proof of any one would be sufficient to establish the practice which is contemplated by the act. That the defendant did in the present case at least attempt "to prevent, relieve, correct, or cure any disease," concluded the court cannot be seriously questioned. The judgment of conviction was affirmed.—*Peters v. United States*, 128 F. (2d) 300 (1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Dietary Ratios in Diabetes—Jackson and Kenefick used 4 children with diabetes mellitus of recent onset as subjects after their exogenous insulin requirement under controlled conditions was definitely established. Each child received their standard diet designed to meet all the known nutritional requirements. The diets were based on a unit formula of 7 Gm of protein, 15 Gm of carbohydrate and 11 Gm of fat, with a fatty acid dextrose ratio of 1:15. The food was given in three meals. This dietary regimen was then changed for approximately one week to a diet of high carbohydrate content and then for about the same time to a diet of high fat content. Each diet had the same caloric value and was always adequate as to nutritional requirements. Two times a week a series of blood sugar analyses was made for each subject. No difference in the utilization of any of the three diets was noticed. The insulin requirement remained constant, and the blood sugar fluctuations approximated the normal range in each study. The high carbohydrate meals were absorbed more rapidly, resulting in slightly higher postprandial blood sugar values. Sugar was not excreted in the urine. On the high carbohydrate diet the 10 p.m. blood sugar values were slightly higher than the 11 a.m. values, but this was probably because the children retired at 7 p.m. and hence had less exercise after the evening meal than in the morning. The close range of the blood sugar

values during fasting implied that the carbohydrate metabolism of these stabilized patients with diabetes mellitus was comparable to that of normal persons. The basic nutritional requirements of the child with diabetes mellitus should not differ from those of the child who does not require exogenous insulin.

Control of Sylvatic Plague—Stewart points out that all mammals (ground squirrels, mice and skunks) in ground squirrel burrow systems fumigated with 2, 3 and 4 ounces (60, 90 and 120 cc) of carbon disulfide per burrow opening were found dead. However, the effect on the adult fleas, both in the nests and on the dead hosts, was not lethal. Methyl bromide should be employed when sylvatic plague is known to exist in the rodents. This is necessary because there is no assurance that the burrow openings which were closed during fumigation will not be reopened by migrating mammals before the surviving fleas die of starvation. This would permit the escape of infective fleas searching for a blood meal. The employment of methyl bromide as a fumigant for fleas and ground squirrels in plague suppression is particularly important where military personnel are quartered and especially when they maneuver in areas containing infected rodents.

Gynecologic and Other Implications Which Relate to the Aging Female Population G W Kosmak New York—p 897

Development of Pelvic Conformation—Morton discusses the evolution of the shape of the female pelvic inlet and the development of the sexual differences in bony pelvis. He examined 10 fetal female and 17 male pelvis varying in age

from 3½ to 10 months, and the pelves of 98 girls and 45 boys varying in age from 3 to 18 years. He found the shape of the inlet to be broader than it was long at all periods of fetal life. There were no significant sexual differences. In children less than 6 the inlet was still either broader than long or round in most instances. From 6 to 11 the pelvic inlet was invariably longer than broad. Before puberty the outline showed an inward bowing in the acetabular regions, presumably resulting from the upward thrust of the femurs. After puberty the pelvic inlet of the female pelves tended to flatten, so that many again became broader than long. No significant sexual differences were observed in the fetal period. In the years before puberty a comparison of the roentgenograms of male and female pelves revealed in male pelves a shorter posterior segment at the pelvic inlet and a downward angulation of the sacrum. The well known characteristics of adult male and female pelves were observed after puberty. A common type of pelvis up to puberty suggests that sex hormones play a large role in its development. Hereditary, nutritional and possibly other as yet unknown factors may also play a role.

Morphine Sulfate as Obstetric Analgesic—The reports of clinically normal babies being born after large doses of morphine had been administered to their mothers prompted Menger to inquire into the actual and potential dangers of using it as an obstetric analgesic. A total of 564 women received morphine alone or in combination with some other analgesic drug. A comparison of 727 women receiving no analgesia, of those with morphine alone or in combination and of the 243 given all other analgesic drugs indicates that morphine, alone and in combination, was associated with the highest percentage of respiratory and circulatory difficulties at birth and of fetal death. Also low forceps operations were three times higher among these patients than among those receiving other analgesics and nine times greater than in the control group. After certain standard exclusions (extraneous factors other than the analgesic) were made the discrepancies for no analgesia, morphine alone and sodium pentobarbital alone were not so large. Nevertheless, morphine still appeared to be attended with considerable respiratory embarrassment, some interference with breast feeding, too many fetal deaths and too many low forceps operations. The factors which combine to determine the effect of the drug on the newborn infant are the time of its administration in relation to delivery, the trauma of labor, the size of the dose, the anesthetic and accessory drugs. Its administration during the second and third hours preceding delivery should be avoided. There is no good reason to discontinue its use completely as an analgesic in normal labor, but its limitations must be recognized.

Sulfadiazine Iontophoresis—Experiments with sulfapyridine, sulfacetamide and sulfadiazine iontophoresis were carried out by Sallmann on rabbits under general anesthesia. Greater amounts of sulfadiazine than of the other drugs entered the eye by iontophoresis. The drug remained in the anterior parts of the eye for four hours in a bacteriostatic concentration. When there was an ulcer or an abrasion of the cornea, a still greater amount was found. The results of sodium sulfadiazine in pyocyanus infection of the rabbit cornea were superior to those obtained with other local or general methods of treatment. The results were still more favorable when iontophoresis was com-

bined with sulfadiazine orally and when treatment was initiated within eighteen hours of the inoculation of pyocyanus. The most favorable treatment twenty-four to thirty hours after inoculation was sodium sulfadiazine iontophoretically and sulfadiazine powder locally and orally. The experimental results of this therapy of advanced pyocyanus ulcers of the cornea have been confirmed clinically in 2 cases.

Sterility of Sutures—From his twelve year survey of the status of the sterility of fourteen American made surgical catgut sutures, comprising 1,381 lots and 17,386 sutures, Clock found that only five brands (the products of five different manufacturers) were uniformly and continuously sterile every year. The first seven years of the study revealed that certain sutures were subjected to entirely inadequate heat or none was used for sterilizing them, reliance having been placed on chemical methods of sterilization. Since then much improvement has occurred by the adoption of an improved bacteriologic method that the author has perfected and that has been accepted by workers everywhere and has been adopted with certain additional procedures and modifications by the United States Pharmacopoeia XI as the standard technique for "Tests for the Sterility of Solids," which test is now enforced by the Federal Food and Drug Administration.

Immediate Covering of Denuded Skull—Dorrance and Bransfield suggest that whenever the pericranium of the skull is removed surgically or by trauma the defect should be covered immediately with a full thickness pedicle flap of adjacent scalp. The pedicle flap is raised from the pericranium but does not include it. The defect created by the pedicle flap has pericranium for its base and may be covered by a free graft from the abdomen or thigh.

Occasionally Positive Sputum—The management of the patient whose sputum after adequate therapy is occasionally positive and a complete clinical reappraisal reveals no obvious source of the bacilli, Stokes says, will largely depend on economics. In arriving at an equitable decision as to what patients shall be isolated and what ones are to return to their former environment the type, age and extent of the pulmonary lesion, the age, sex and resistance of the patient, his intellectual and economic status, his economic usefulness, his personal, family and civic responsibilities and finally his vocation must be considered. The presence of any bacilli in the sputum of patients less than 25 is of serious import and almost always indicates the necessity for further active treatment. The careless patient and sanatorium "repeater" must be permanently isolated. The actual dollar cost of this may well be less than caring for secondary contact cases. The patient whose disease is healed by extensive fibrosis which reduces his pulmonary reserve to the point that he is a permanent respiratory cripple and who can never be rehabilitated must also remain under custodial care. Rarely it may be necessary to extirpate surgically a focus that may be shedding occasional tubercle bacilli, notably the post-tuberculous bronchiectasis. However, the management of these patients cannot stop here. The physician has a moral obligation to see that treatment remains constantly adequate. The contacts of these patients should have roentgenograms of the chest taken periodically. Never should these patients be allowed to engage in occupations that require the handling of children or food.

Tuberculin Test in Bone Tuberculosis—Howard and his associates carried out the tuberculin test for ten years on 19 children with bone tuberculosis. The initial threshold reactions of 4 children at the start of the involvement were 0.1 to 0.01 mg of old tuberculin. These levels subsequently rose to 0.0001 to 0.0000001 mg and then receded again to levels of 0.01 and 0.001 mg with the healing of the process. The sensitivity of a group of 7 children followed the same rise and fall but these children did not appear for treatment at the start of bone involvement. The allergy pattern of 5 children showed

a high plateau of sensitivity for from three to six years associated with a poor healing ability and the death of 1 patient from constant spread of the tuberculous infection. All children showed a positive test at the start of infection. 1 four months before bone destruction could be seen on the roentgenogram. It is concluded that a rise to a high level of sensitivity with a subsequent fall is characteristic of the evolution of the healing process in bone tuberculosis and that sustained high levels of allergy have characterized lesions which have failed to heal.

Survival of Tubercle Bacilli in Books—To determine whether books and magazines handled by sputum positive patients are infectious, Smith smeared artificially or naturally positive sputum in 0.05 cc amounts on 1 inch squares cut in but not removed from the leaves of books, magazines or stacks of paper. The books were immediately closed while the pages were still wet and stored in a dark cupboard in an unheated room. At intervals these paper squares were removed with sterile forceps and shaken by machine with a weak alkaline solution to recover the tubercle bacilli for culture and guinea pig inoculation. The tubercle bacilli remained alive for two weeks to three and a half months. They were not recoverable at from three weeks to five months. In general, they lived about as long on paper as on glass. They lived as long on printed as on blank paper. The period of recoverability was longer when the dose was large and was deposited during the winter season when average temperature and relative humidity were lowest. Occasional uncovered coughing into books is fairly common among sanatorium patients. Thumb wetting occurs but is infrequent. Therefore books and magazines used by sputum positive patients are possible sources of infection. They should not be read by nontuberculous persons. Contaminated books ought to be rendered safe and noninfectious in most cases by a quarantine period of one month.

Shock—Shock is initiated by any factor that causes an acute but persistent diminution of the minute volume of the circulation. This reduction may be of cardiac origin due to loss of plasma externally, due to a primary combined diminution of blood volume from increased capillary permeability and/or an increase of the capacity of the circulation caused by dilatation of capillaries and venules. With the latter a change in the chemical or physical character of the blood may also impair the general circulation. When the diminished circulation throughout the body of itself increases permeability and dilatation of the capillaries and venules it augments the already impaired capillary function. When this begins to occur, true shock is said to be present. In part at least, by direct effects on the capillaries such substances as anesthetics, heparin, dyes, toxins and other chemical agents in excessive quantities may also contribute to or even induce shock. Most of the symptoms of shock are explainable on the basis of the depression of the circulation and the associated depression of the functions of the body. Because shock tends to perpetuate itself once the minute volume of circulation has become sufficiently decreased it is most important to prevent the initiating factors and to restore the blood volume before the vicious cycle is firmly established and before irreversible damage occurs in the various tissues of the body. Green is convinced that it is better to give fluid, preferably blood, during an operation, even though it is continuously lost by unavoidable hemorrhage, than to allow the blood pressure to become dangerously low and then, to attempt to restore the fluid loss after the operation is completed. The term shock for

this condition is unfortunate as it implies something sudden, whereas shock appears to be a relatively slowly developing progressive condition, for which an apt term would be acute progressive circulatory failure.

Insulin Shock During Sodium Pentothal Anesthesia—The management of the anesthesia of a diabetic patient undergoing surgical intervention includes the administration of insulin, saline solution and dextrose, preoperatively and postoperatively. During anesthesia the symptoms (nervousness, tremor, anxiety, irritability and convulsions or coma) of insulin shock are not present in the anesthetized patient. To establish criteria whereby insulin shock during anesthesia could be recognized, Papper and his colleagues studied the insulin shock in 3 volunteer normal men aged 25 to 32. They were admitted in an acute alcoholic episode but were clear mentally, were cooperative and were not nutritionally deficient. Insulin shock was induced during cyclopropane anesthesia and during pentothal sodium anesthesia by an initial intravenous injection of 30 units of insulin and 20 units for three doses every half hour. The first injection was given after a dextrose tolerance test during anesthesia, that is, two and a half hours after the intravenous administration of 100 Gm of dextrose. Experiments were conducted seven days apart in the postabsorptive state. Anesthesia was maintained in the surgical second plane. Premedication drugs were not used. The first evidence of insulin shock was moderately profuse perspiration one hour after the first dose of insulin during pentothal sodium anesthesia, with cyclopropane profuse perspiration occurred one and a half hours after the first dose of insulin. The perspiration was followed in twenty minutes by an increased pulse pressure (due almost entirely to a fall in diastolic blood pressure), a slight tachycardia and a full bounding pulse of the Corrigan type. These manifestations of insulin shock were the same with the two agents except that the latent period was longer with cyclopropane. The administration of dextrose intravenously reverses the changes immediately. The rise in pyruvic acid levels during pentothal anesthesia was decided, whereas with cyclopropane if they changed they were decreased. Cyclopropane, while affecting the fasting blood sugar level little, caused definite changes in the dextrose tolerance curve with a diabetoid type of reaction. This impairment was less definite with pentothal anesthesia.

Electrocoma Therapy of Psychoses—The clinical results of electrocoma shock therapy in 70 patients with various mental disorders are recorded by Fetterman, who offers some interpretation of the results obtained in the light of the modern concept of psychoses. Although the clinical results of the therapy have been extremely satisfactory, certain disturbing but usually temporary reactions occur. They are decided amnesia, periods of elation and states of confusion. In addition to these psychological side actions, which are temporary, certain complications, possibly of a more permanent nature, of electrocoma shock therapy may be divided into immediate reactions and possible later sequelae. The immediate complications are chiefly the injuries to the muscular and bony systems, and the possible late sequelae are cerebral, which Cerletti and Kalmowsky believe are reversible

and do not produce serious damage. The most significant clinical observation is the high rate of improvement and the willingness of the patients to take this treatment. A course of electrocoma treatment influences the mood of the patient first. There is a tendency for the saddened patient to become more cheerful. In patients who are troubled by serious hallucinations and delusions this improvement in mood pushes into the background the hallucinatory experiences, which are later ultimately lost. Recovery in mental function requires the accumulated benefits from a series of treatments. Previous mental clouding with decided forgetfulness or confusion does not interfere with recovery. Recovery is obscured by the clouding, but despite this delay the clouding lifts and the goal is reached. The treatment achieves its success through direct electrical or chemical alteration in cerebral functions. The therapeutic effect is not attained through fear, patients do not emphasize any terror reaction as they do with metrazol. Recovery is highest in depressed patients, there is improvement in many with schizophrenia, and there is a tendency toward improvement in manic states. During treatment there is a change in the patient's direction of interest and thought. He tends to look outward, to notice external stimuli and to interpret them in line with reality. Recovery is thus not so much a gain in total cerebral function as an improvement in the direction of thought. On the basis of these observations, Fetterman makes the following conjectures. The brain is the seat of or the major link of all psychoses which are caused by disturbances in cerebral function and are believed to be organic, even if the disorder cannot be established microscopically. The mechanism of recovery depends on an electrochemical change in cerebral cells. Each treatment appears to damage the function of either cortical cells or association pathways, and thus those elements which are responsible for the abnormal direction of thought are either reduced or destroyed. The damage is reversible and there is a tendency for the abnormally functioning cells to regain their activity. Each succeeding treatment removes this tendency. In the depressions, when this change has been effectively brought about, recovery ensues. In many types of schizophrenia this improvement is temporary because there is an inherent tendency for a downward course. One is sometimes surprised at the renewed intellectual interest in life that is awakened in an apparently deteriorated patient following the therapy. Only time can determine the permanence of recovery and the possibility of later complications.

Chronic Constrictive Pericarditis—A follow up study of 37 patients with constrictive pericarditis that Harrison and White saw at the Massachusetts General Hospital and in whom the clinical diagnosis was confirmed in all but a few at operation or at necropsy is presented. Nineteen of the patients are living, 17 are dead and 1 has not been examined lately. Twenty eight of the group have had pericardial resection and 9 have not. The average age of the entire group was 30.2 years of those operated on 28.8 years and of those not operated on 45.5 years. Fourteen of the 28 operated on were clinically cured although in a few a slight increase in venous pressure above the average normal remains, and 1 of the 14 died of pneumococcal pleurisy a year after operation. Of the other 14, 3 were much improved, 2 died of the disease itself, the death of 5 was related to the operation and 4 died of other complications from one month to seven years postoperatively. The condition of 3 of the 9 who did not have pericardial resection was so mild that operation was not necessary, 3 were too ill to undergo operation, 1 died of military tuberculosis before the operation could be carried out, 1 died before this type of operation was begun and 1 patient was lost sight of.

Surgical Treatment of Hypertension—During the last ten years, according to Bartels and his collaborators, 54 patients with hypertension have been operated on at the Lahey Clinic. This is sufficient time to justify an evaluation of the results. The first 13 patients were subjected to a supradiaphragmatic splanchnicectomy and gangliorhizotomy and the others to a two stage subdiaphragmatic or transdiaphragmatic resection of the greater and lesser splanchnic nerves, with the removal of the twelfth thoracic, first and second lumbar ganglia, the visualization of the adrenal glands and biopsy of each kidney. If a sufficient amount of omentum was available, the left kidney

was decapsulated and a nephro omentopexy was carried out, but if large accessory arteries penetrated the capsule of the kidney or the omentum was adhesive from previous operative procedures nephropexy was not attempted. The results confirm the experiences of others that surgery of the sympathetic nervous system may have an ameliorating effect on the blood pressure of patients with essential hypertension. The best results were obtained on patients with grade 2 or 3 hypertension whose ages were less than 40 and whose blood pressure responded to sedation. Age appears of considerable importance in selecting patients likely to obtain a satisfactory drop in blood pressure. Of 20 patients more than 40, only 2 had a drop in blood pressure as against 22 of 32 less than 40. Of the patients more carefully selected, 13 (34 per cent) of 38 had an excellent result and 11 had a slight drop in pressure. The blood pressure of the others was not altered. Symptomatic improvement occurred in 71 per cent, in half of these the blood pressure remained elevated. The operation appears justified when patients fulfil the selective criteria and when they understand that satisfactory lowering of the blood pressure is obtained in about one third of the cases.

Physiologically Directed Therapy in Pneumonia—Barach proposes to show that recent advances in physiologically directed treatment may crucially alter the course in bronchopneumonia or lobar pneumonia of patients who do not respond to sulfonamide compounds. The measures employed were the administration of positive pressure, inhalations of helium-oxygen mixtures and inhalation of the vaporized solutions of neosynephrin and epinephrine. In the treatment of 4 patients with bronchopneumonia of undetermined origin and of 1 with lobar pneumonia the physiologically directed therapy was of crucial value as regards anoxia, respiratory obstruction and pulmonary edema. The importance of maintaining respiratory function in pneumonia and bronchopneumonia not responding to specific chemotherapy was illustrated by the response of the 5 patients to inhalational therapy.

Toxoplasmic Encephalomyelitis—Cowen and his colleagues encountered 6 children who exhibited some or all of the features of infantile or congenital toxoplasmosis. Toxoplasmas have been isolated and positive serologic reactions have been obtained from all. Nine other instances were recognized at necropsy. Most of the latter 9 children died during the early weeks or months of life in the acute or subacute stage. The syndrome was characterized by the concomitant occurrence in infants at or soon after birth of multiple focal, bilateral areas of chorioretinitis, microphthalmos, nystagmus and ocular palsies, and of convulsions, hydrocephalus and multiple foci of intracerebral calcification. The first 6 clinically identified cases in which survival beyond infancy occurred indicate that, contrary to previous experience, the infection is not uniformly fatal and may become chronic, healed or latent. The clinical picture consists chiefly of the residual effects of the lesions occurring in the acute or the subacute stage. The principal symptom is usually diminution in vision due to the effects of multiple foci of healed chorioretinitis, which are readily identifiable ophthalmoscopically. Strabismus, microphthalmos and minor congenital ocular defects may also be present. Generalized convulsions or

petit mal attacks may persist or make their appearance later. Internal hydrocephalus may become chronic and progressive. Foci of intracerebral calcification persist and may at first increase in number and size. Retardation in the development of speech and minor degrees of mental deficiencies occur. In many, if not all, the disease was congenital, therefore this form of toxoplasmic encephalomyelitis should be referred to as infantile or congenital to distinguish it from that which may be acquired during the juvenile period and in adult life. Infantile or congenital toxoplasmic encephalomyelitis is evidently not a rare disease, many cases have probably been erroneously classified as congenital malformation of the brain, cerebral birth injury, epilepsy, congenital hydrocephalus and the like. The identification of additional cases may suggest the epidemiology of the disease. At present the infection appears to be widespread in the United States, it also has been encountered in South America and Europe. Various mammals, and perhaps birds, are probably the animal reservoirs of the infection. The mode of transmission to man is not yet known.

Toxic Myelopathies—In most cases of toxic myelopathy following arsphenamine therapy the changes in the spinal cord are so different from those in the brain that doubt arises as to the pathogenic relationship between the action of the drug and the alterations. Lichtenstein reports the data of his case and a review of similar ones recorded in the literature. The microscopic changes in his case consisted of extensive areas of demyelination in the central portions of the thoracolumbar segments of the spinal cord and of focal areas in the medulla oblongata, dense perivascular infiltrations with lymphocytes and plasma cells in the demyelinated areas and similar infiltrations in the forebrain and in the spinal cord unassociated with alterations in the parenchyma, focal leptomeningitis in regions in which the leptomeninges bordered on demyelinated tissue, proliferative alterations in the astrocytes in the demyelinated areas and slight degenerative changes in the peripheral nerves. No foci of softening, necrosis or signs of secondary degeneration were present. Postarsphenamine toxic myelopathy is apparently more common in the male than in the female, all the reported cases have occurred in adults. Most of the patients were symptom free prior to the myelopathy, the positive serologic reaction was the only abnormal finding. The onset of the myelopathy and the time of the syphilitic infection varied from a few years to forty. The only definite relationship was the onset of the myelopathy in a day to many weeks after arsphenamine therapy. The presenting motor or sensory symptoms, which were soon followed by flaccid paralysis, were referable to the lower extremities. With severe involvement urinary retention occurred early, and when the process was slow difficulty in micturition was present for some time before retention developed. The course of the disorder is characterized by an ascension of the motor and sensory disturbances, and for this reason many cases have been described as instances of Landry's paralysis. In the acute form, in which the disorder spreads to the medulla, death from respiratory paralysis may ensue in two weeks, and in the subacute form as much as ten weeks may elapse between onset and death from respiratory failure. Rarely the upward spread of the disorder stops spontaneously and the patient may be discharged with flaccid paralysis of the lower extremities, anesthetics and sphincteric disturbances. When the evolution of the disorder is slow, death may occur from sepsis or pneumonia. Another wrong diagnosis made frequently is syphilitic myelitis. Such a diagnosis is dangerous as it may cause the clinician to give more antisyphilitic treatment, which may hasten the progress of the disorder.

Destruction of Hypothalamus by Tumor—The clinical and pathologic sequelae of a slowly growing tumor which involved the floor and walls of the third ventricle and destroyed all nuclei of the hypothalamus and severed functionally the hypothalamic stalk, but which did not disturb the adjacent regions or obstruct the flow of cerebrospinal fluid, is reported by Collins. The following abnormalities were ascribable to the destruction of the hypothalamus by tumor: diabetes insipidus, suppression of the function of the anterior lobe of the pituitary, the thyroid, the ovaries and the adrenal glands and the disturbance of fat metabolism, sleep, thermal regulation and personality. The role of the thyroid in diabetes insipidus is demonstrated, and infor-

mation bearing on the anatomic and physiologic relationship between the hypothalamus and the anterior lobe of the pituitary gland is presented

Iodized Poppyseed Oil—Craig studied the toxicity on the spinal cord and meninges of iodized poppyseed oil 40 per cent from an experimental point of view. In the experiments he made an attempt to adjust the amount of the oil injected to the size of the dog so that it should be comparable to the maximal amount used clinically. The 6 dogs used were killed fourteen to three hundred and fourteen days after injection. In 5, examination of the spinal cord revealed that an inflammatory process involved the leptomeninges and the spinal blood vessels. The reaction tended to be more acute in animals killed early than in those killed late. A lesion within the cord was not observed in any dog. In 1 dog there was no reaction. These experimental results are at variance with those of other investigators, and it is suggested that the difference is related to the relative amount of the oil injected.

Retrobulbar Neuritis—Benedict reviewed the records of more than 400 patients with retrobulbar neuritis, seen at the Mayo Clinic between 1920 and 1940, to determine whether patients for whom a tentative diagnosis of multiple sclerosis was made experienced further evidence of the disease. By eliminating other factors which might cause blindness, multiple sclerosis was suspected in 90 of the 400 patients. In 41 of the 90 further evidence of the disease has appeared. In not 1 of the remaining 49 have the retrobulbar neuritis and the scotoma been found to be due to another cause. At the first appearance of blindness it was often possible to make a diagnosis of arteriosclerosis, diabetes, cerebral tumor, encephalitis, arachnoiditis and neuritis arising from exogenous toxins as the cause of the retrobulbar neuritis. Sometimes a tentative diagnosis was made of one or another of these probable etiologic factors, for example, alcohol-tobacco amblyopia, just as at other times multiple sclerosis was suspected because of the history and of the ocular and general symptoms. It seems reasonable to the author, in the absence of signs or symptoms of other causes, to presume that the retrobulbar neuritis is due to multiple sclerosis, even though the etiology of the disease cannot be substantiated on any other grounds.

Tuberculous Iritis—Brown, Irons and Rosenthal observed that the exposure of 2 patients with tuberculous iritis recurrent for four and thirteen years, respectively, to the inhalation of fumes from saline suspensions of dead tubercle bacilli was followed by a definite reduction of sensitivity for two years. This was determined by periodic titrations with dilutions of tuberculin administered intracutaneously. No final conclusion can be arrived at from the observation of only 2 cases, but for the present the authors wish to report only what they observed. The inhalation method was discovered accidentally in the Tice Laboratory of the Municipal Tuberculosis Sanitarium of Chicago. In certain members of the laboratory staff symptoms varying from malaise to chills, fever up to 104 F., a tickling sensation in the posterior part of the pharynx, cough, vomiting, headache and backache developed periodically. After several months the attacks lessened and finally abated. Previously positive reac-

tions to tuberculin tests of these affected persons were decreased. It was inferred that the issuing vapors might be the causative agent, and experimentation on more than 100 guinea pigs confirmed the assumption. The agent responsible for decreasing sensitivity is not known, but some volatile substance is suspected. In planning inhalation treatment for their first patient the authors had no experience other than that with the guinea pigs to guide them.

Adie's Syndrome—The following conclusions are given by Lowenstein and Friedman in their discussion of Adie's syndrome. 1. Pupillomotor reactions may be caused by postganglionic and preganglionic peripheral lesions of the third nerve and by lesions in the great vegetative centers of the diencephalon and their connections with the mesencephalon. 2. Adie's syndrome, characterized by pupillomotor reactions with irritative sympathetic symptoms and absent tendon reflexes, is due to a hereditary degenerative disease localized in the great autonomic centers of the diencephalon and their connections with the mesencephalon. It generally is not of syphilitic origin, but as a syndrome it may be produced by asymptomatic syphilis nervosa. 3. As the nervous manifestations of congenital syphilis are more frequently localized in the sympathetic center than are those of acquired syphilis, it is possible that in some cases the syndrome is due to congenital syphilis. 4. The pupillographic picture of Adie's syndrome is generally unequivocal. 5. Physostigmine contracts the Adie pupil (as it does the normal pupil) and restores its ability to react to light and to dilate to distant vision in twelve to twenty minutes after its local application. 6. The physostigmine test enables one to differentiate Adie's syndrome from similar syndromes due to acquired syphilitic infection. 7. Neurotonia (prompt contraction of the pupil to light but sluggish and retarded dilatation and diminished or absent convergence reaction) appears to be an inversion of Adie's syndrome. The relation with Adie's syndrome is that either syndrome may be substituted for the other in the hereditary sequence, therefore the basic processes must be considered identical. 8. The entities neurotonia and pupillomotor pseudotabes include many minor and abortive forms which can be detected by pupillography, they are rather frequent anomalies and have the value of a focal degenerative stigma in the nervous system.

Atrophic Rhinitis—The intimate relation of the vascular supply of the nasal and of the nasopharyngeal mucosa suggested to Ruskin a direct hormone action of the pharyngeal pituitary on the nasal mucosa. This led him to study the physiologic properties of the pharyngeal pituitary in mice, with the result that a hormone mechanism related to the pituitary gland and possessing estrogenic properties appeared to be a normal constituent of the nasal mucosa. He and others have since tried clinically (1) a nasal spray of estrogen in oil alone, (2) a nasal spray of estrogen in oil combined with parenteral injections and (3) oral administration of estrogen tablets. The combined nasal spray and parenteral injection of estrogen in oil appeared the most effective. Amniotin in oil and *a*-estradiol dipropionate as a nasal spray have seemed equally effective. One patient

was given diethylstilbestrol in oil, 10,000 international units of estrogen per cubic centimeter, for three months. During this time the patient used intranasally as drops three 10 cc vials, a total of 300,000 international units. There were no unpleasant by effects. The nasal mucosa appeared to be definitely improved, and the patient has not required more than an occasional observation for more than a year. The crusting had diminished, and there was little nasal discomfort. Diethylstilbestrol may further aid the therapy of primary atrophic rhinitis (ozena). However, the first essential is to differentiate between primary atrophic rhinitis of vascular origin and secondary atrophic rhinitis from severe nasal infection.

Glossopharyngeal Neuralgia—True glossopharyngeal neuralgia is extremely rare. In the approximately 30 cases that Street collected from the literature the clinical picture was strikingly uniform. The unilateral excruciating paroxysms of pain always strike some part of the glossopharyngeal sensory area—the tonsil, the back of the tongue or the pharynx. The pain is variously described as lancinating, as knifelike or as a stab of a red hot iron. Each pain usually lasts only a few seconds. The paroxysms tend to occur in a series over a few days to a few weeks, in nearly every case intermissions of several months have occurred. The pain usually radiates to the ear, the tongue and ear or the tongue and pharynx. The method *par excellence* of starting attacks of glossopharyngeal neuralgia is to drink hot or cold liquids—cold is most effective. The attacks may also be induced by swallowing talking, yawning, coughing, shouting, sneezing and touching the angle of the mandible. Often the attacks seem to occur spontaneously. For treatment the injection of alcohol is not to be considered, as the glossopharyngeal nerve is extremely near the vagus nerve and large blood vessels. Therefore surgical procedures (external approach for extirpation of the glossopharyngeal nerve in the neck and intracranial section of the glossopharyngeal nerve) must be resorted to. The latter gives complete and permanent relief. If this procedure is contraindicated peripheral section, which is complicated, difficult and delicate but possible, can be performed. The subjective signs of section are anesthesia of the retropharynx and tonsil on the affected side and loss of taste in the posterior third of the tongue. The swallowing of solids may also be interfered with. If extreme hypertension or cardiovascular disease contraindicates intracranial intervention, section and extirpation of the glossopharyngeal nerve in the neck are means of obtaining relief. The greatest difficulty in this operation is to recognize the nerve.

Estrogen Metabolism—The data that Pincus and Pearlman present demonstrate a close resemblance in the physical and chemical properties of the estrogenic material of the three principal urine fractions and those of the presumed corresponding crystalline estrogens. The principal phenolic fractions of the pooled urines of 8 male and 13 female patients (with no

endocrine disorders) were the strong phenolic, the weak phenolic nonketonic and the weak phenolic ketonic. By the application to such fractions of certain partitioning between solvents and an alcoholic separation, evidence was obtained that these three principal fractions behave as though they contain theelin, dihydrotheelin and theelin. After injection of theelin the titer of all three fractions increased. The calculated recoveries indicate a conversion of the injected theelin principally to thecol but also to dihydrotheelin. Less than 2 per cent of the injected estrogen could be accounted for by increased urinary excretion. Although the female patients had higher preinjection levels, the calculated recoveries in the urine showed no decided differences between the sexes.

Cutaneous Reactions and Desensitization to Histamine—Browne describes the response of the skin to gradually increased intradermal injections of histamine. He observed that histamine flares, to be correctly evaluated, must be produced under a constant environmental temperature, a standard posture of the individual and the arm to be tested, a standard source of light and a uniform technique. A room at 78 F with 40 per cent humidity and the patient in the supine position with the arm at a straight angle was satisfactory. A 75 watt Mazda lamp 2½ feet above the flare zone is preferable to daylight for the reading of flares. It appears that only a slight change in cutaneous temperature is necessary to cause a great change in the area of the flare. The most useful dilution of histamine for cutaneous testing was 1:100,000 (histamine acid phosphate used, dilution calculated as base). The histamine wheal is not a good criterion to use in comparative studies of endermic reactions. Histamine flares provoked at intervals over a period of approximately two weeks in subjects treated with gradually increasing amounts of histamine administered subcutaneously twice a day disappear in 40 per cent of cases, are significantly reduced in 25 per cent and are insignificantly changed in 35 per cent. There is an apparent correlation between the clinical result of treatment and the state of the histamine flare. If the cutaneous reaction is assumed to be an index to systemic desensitization (as it is in allergic states), it can be said that 40 per cent of the patients treated showed a complete desensitization, 25 per cent partial desensitization and 35 per cent no desensitization. The desensitization phenomenon probably varies in the individual and is perhaps relatively short lived.

Sarcoidosis—Bernstein and Oppenheimer report 6 cases of sarcoidosis and state that, although it is said to be characterized by a generally benign course, 1 of their patients died from diffuse visceral sarcoidosis, 1 is completely invalided as a result of chronic failure of the right side of the heart secondary to advanced pulmonary sarcoidosis and a nephrotic syndrome and 1 has suffered progressive loss of vision due to sarcoid infiltration of the uveal tract. The sarcoidosis of 2 patients is limited to the peripheral lymph nodes without any systemic manifestations and 1 patient, with lymphadenopathy involving the left cervical chain, who had intermittent fever and lost considerable weight, remains chronically ill. Microscopic confirmation was attained in all cases by biopsies of lymph nodes, tonsils, iris or skin. At necropsy the patients who died disclosed diffuse visceral sarcoidosis. The tendency of the disease to chronicity and spontaneous retrogression may at times give a misleading picture of its extent. Positive tuberculin reactions, strong in only 1 instance, were obtained from 4 patients. Tubercle bacilli were never isolated, and associated active tuberculosis was never established. The hematologic picture was not unusual and the sedimentation rate, contrary to the experience of some observers, was not accelerated. Bone changes were not disclosed and 3 patients had no cutaneous manifestations. The temperature of 2 patients exceeded 103 F for relatively long periods. Iridocyclitis was present in 2, hyperproteinemia did not occur and there was a reversal of the albumin globulin ratio with a nephrotic syndrome in 1. Although most observers consider the lesions radioresistant, the authors' experience with roentgen therapy has been most encouraging. Three of 4 patients so treated showed some improvement, and in the fourth a huge mass of cervical nodes disappeared within two weeks. Radiosensitivity may vary with the stage of the disease. In an involutionary phase the response may be much more prompt than when the disease is in the process of evolution and hence radioresistant, this was exemplified by 1 patient whose cervical masses retrogressed but were subsequently resistant and the disease, preceding the patient's death, became widely disseminated. The cause of sarcoidosis remains unknown, there is some evidence of its relationship to tuberculosis.

Ruptured Intervertebral Disks—Since the elimination of contrast mediums in April 1941, Dandy has made a correct diagnosis in 65 cases by clinical examination alone. He believes that iodized oil and air injections into the spinal canal do far more harm than good, their avoidance is most enthusiastically welcomed by the patient. In view of the fact that 96 per cent of all ruptured vertebral disks are at the fourth, fifth and sixth lumbar spaces and since unilateral exposure (hemilaminectomy) is adequate to disclose the disk, regardless of the interspace that is involved, it is only necessary to make the diagnosis of a ruptured lumbar vertebral disk. The diagnosis is almost pathognomonic from signs and symptoms alone.

Lipid Metabolism and Central Nervous System—The diseases of lipid metabolism, according to the type of lipid deposit, are three: amaurotic family idiocy and Niemann-Pick disease, Gaucher's disease and xanthomatosis. Davison observes that the generalized disturbance (deposition) of lipid in amaurotic family idiocy and Niemann-Pick disease involves not only the central nervous system but also the entire reticuloendothelial system. Careful study is required to find a generalized instead of a localized lipid disturbance as seen in the central nervous system. The lipid deposits in the nervous and reticuloendothelial systems consist of phosphatides. In Niemann-Pick disease a specific increase of sphingomyelin has been demonstrated. Gaucher's disease, a disorder of lipid metabolism of the reticuloendothelial system, may occasionally affect the central nervous system. The predominating lipid consists of kersin of the cerebroside group. Xanthomatosis consists of granulomatous masses deposited throughout most of the organs. The calvarium may also be invaded and the nervous system compressed or actually infiltrated. The disturbed lipid metabolism involves the reticuloendothelial system, the predominating substance is cholesterol.

Amaurotic Family Idiocy—Globus gives a brief historical review of amaurotic family idiocy, clinical histories are reviewed briefly and detailed anatomic observations are presented of 12 cases of the infantile form (in 1 case the affliction was combined with Niemann-Pick disease) and of 1 case of the juvenile form of the disease. The clinical and anatomic features of the late infantile, adult and congenital forms are described and their relationship to the entity is discussed. New observations on the ubiquity of the disease process include the disclosure of isolated cell groups outside the central nervous system exhibiting cell alterations characteristic of the disease. Changes in the posterior lobe of the pituitary are advanced and the numerous globoid granular bodies found there are unusually large. The several forms of the disease including one which is associated with Niemann-Pick lipid histiocytosis, belong to a single disease entity characterized by a disturbance in lipid metabolism. Too great emphasis has been placed on focal variations in the intensity of the pathologic process as observed in the several variants of the disease. A study of the endocrine organs in several of the cases which the author reports failed to provide evidence supporting the view that their dysfunction is at the base of the disease process. The presence of nerve cell groups within the territorial domain of some glands of internal secretion (adrenal, posterior lobe of the pituitary body) is thought by him to be no more than an item in the ubiquitous disease process which universally affects nerve cells. The general conclusion is that amaurotic family idiocy is a malformation characterized by defective constructive material in the affected cells or by their (the cells) lack of capacity for assimilating available material. Either of these difficulties is capable of causing regressive morphologic changes, resulting in dysfunction and finally in total disintegration of the affected cells.

*Arteriovenous Fistula Between Ascending Aorta and Superior Vena Cava Report of Case J M Barker and W M Yater Washington—p 439

Arteriovenous Fistula—Barker and Yater report a case in which it was impossible to determine whether one dealt with a superior vena cava occlusion or with an arteriovenous communication between the superior vena cava and the aorta. The patient, a Negro of 44, was admitted to the Georgetown University Hospital complaining of swelling of the eyes, face, neck and the right upper extremity for nine hours. He had been perfectly well until 5 o'clock on the morning of his admission, when he was awakened by a "stiffness and pulling in the throat." Although the diagnosis of spontaneous arteriovenous fistula between an aneurysm of the ascending aorta and the superior vena cava was considered the absence of a continuous harsh murmur with systolic accentuation, thrill, red venous blood and venous pulsations made a definite diagnosis impossible. These signs are evidently not essential for such a diagnosis. The sudden appearance of edema of the upper half of the body with cyanosis and great elevation of the venous pressure in a patient

with an aneurysm of the ascending aorta probably usually denotes the onset of a spontaneous arteriovenous fistula between the aneurysm and the superior vena cava. The only other possible condition, thrombosis of the superior vena cava, is even rarer. The authors' patient died one hundred and eleven days after the onset and death was caused by asphyxia from laryngeal obstruction due to edema of the larynx. At necropsy the anatomic diagnoses were syphilitic aortitis, syphilitic aortic aneurysm of the ascending aorta, arteriovenous fistula between the aneurysm of the ascending aorta and the superior vena cava produced by spontaneous rupture of the former into the latter, varices of the great veins of the head, neck and thorax, stenosis of the glottis due to edema, edema of the upper half of the body and a healed Ghon tubercle.

Disorders of Feet—Morton states that the most direct cause of metatarsalgia trouble is shortness of the first metatarsal, the second source is a rearward position of the sesamoid bones and the third and most common cause is a looseness or laxity of the basal joints of the first metatarsal segment. The whole range of symptoms are not unlike those present in any other chronically strained joint persistently subjected to continued strains of similar violence or intensity. Therefore cases of chronic joint strain are due to improper weight distribution, and the symptoms are maintained and exaggerated through daily persistent abusive function. Consequently the immediate phases of treatment are (1) restriction of activities and weight bearing in accordance with the severity of symptoms, (2) rest, (3) fre-

quent brief periods of rest during the day with the legs and feet supported at hip level, (4) removal of all sources of surface irritation (corns, calluses, warts) and avoidance of badly fitting shoes, (5) contrast plunges daily (late afternoon preferably) to counteract the irritative effects of each day's activities and to establish improved circulatory conditions and (6) other therapeutic measures (physical therapy or drugs) as indicated. The signs of faulty shoes and those due to internal foot disorder must be distinguished. A helpful working rule is to assume (in general) that pain on the top and sides of the foot calls for a check on the shoe, when it is on the bottom or the sole of the foot the trouble is generally inside the foot. At least a dorsoplantar roentgenogram should be taken of both feet in every case. Soft tissues and nerves that have been more or less irritated for months or years do not become normal in a few hours or days. Permanent results require intelligent and patient treatment.

*Criteria for Diagnosis of Brucellosis J F Griggs Claremont Calif—p 389

Criteria for Diagnosis of Brucellosis—The route well known form of brucellosis is characterized by a high, usually persistent, fever and profuse perspiration. The patient may feel as if he had a severe, prolonged influenza or dengue fever or he may be remarkably comfortable and clear headed for the severity of his fever. Physical changes are rare but an enlarged spleen may be present. The diagnostic criteria are a positive blood agglutination test, a positive blood culture, a leukopenia relative to the fever, a history of consuming raw milk or its products, the handling of infected cattle or their excreta or exposure to *Brucella* in the laboratory. For a positive diagnosis of the chronic form Griggs declares, the first criterion is a really ill patient. A long and searching history must be taken otherwise the disease is not likely to suggest itself. The typical history reveals a rather long total period of ill health. The course may be an undulant one with some constraining features or it may include complete remissions of good health interspersed with recurrent periods of vague or atypical illness. The symptoms may be decidedly varied. The history often suggests a psychoneurosis. The temperature should be taken daily in the late afternoon for at least five minutes. Fever, if present, reveals that a probable infection is present. However, fever may be absent in active chronic brucellosis. When fever is present it should be compared with other observations particularly the blood count. If it is absent the diagnosis must be confirmed by other data. The physical examination, except for fever, is negative as is the roentgen examination except for pulmonary or bone lesions in about 5 per cent of patients. The bone lesions show destruction of cortical tissue in a localized manner with a relative absence of periosteal reaction. The blood picture may vary widely, but it tends to show a relative lymphocytosis and leukopenia and/or a mild anemia with a high color index. The exclusion of other probable or possible diseases is most important. Coincident conditions must be identified and assigned their proper share in the total symptomatology. The power of the polymorphonuclear leukocytes to ingest living *brucella* organisms from a fresh culture of fresh citrated blood should be tested before cutaneous or vaccine tests are performed. If some of the patient's cells ingest as many as thirty-one or forty or more bacteria and if all phagocytose some bacteria, the test is diagnostically significant. Like the agglutination test, this opsonocytophagic test is not an index of infection but an expression of specific resistance. A positive test is only a part of an integrated diagnostic pattern. The blood agglutination test is the least useful of all the tests in the diagnosis of chronic brucellosis. However, if positive it may be significant of probable brucellosis. Positive cultures of *Brucella* from the blood or other body fluids are irrefutable proof. The intradermal test, performed after the blood tests

and fever record are completed, is the most important of the objective tests. If other tests are conclusive the cutaneous test should be omitted, as necrosis of the skin or premature desquamation of epidermis (near necrosis) is easily caused by a strong concentration of *brucella* protein in sensitized persons. A definitely favorable response to *brucella* vaccine therapy is diagnostically confirmatory. This therapeutic test may not be evident until after months or years of therapy. An unfavorable but diagnostic reaction is hypersensitivity, that is, local tissue intolerance, to vaccine. If this is anticipated, it can and should be avoided. The diagnosis emerges out of certain combinations of diagnostic data and not from any one or two air tight criteria.

Carious Lesions in Molar Teeth of Hamsters—Arnold's studies indicated that diets containing cereal, like those used to induce caries in rats, were also effective in hamsters. He determined whether the size of the cereal had the same etiologic influence on dental caries in hamsters as it does in rats. Carious lesions were not as was the case in rats, dependent on the coarse particle cereal in the diet, as caries was most extensive in animals fed a finely ground cornmeal ration. This result suggests the possibility of adapting a strictly synthetic diet to the study of experimental caries in these animals. The two distinct types of lesions observed were caries in the pits and fissures of the occlusal area of the molar teeth and caries in the cervical portions of the proximal surfaces, mostly in the upper and lower first molars.

Bagassosis—According to Castleden and Hamilton Paterson, directly after machinery was installed for dry bale-breaking of bagasse (the waste of sugar cane after the sugar has been extracted), instances of respiratory illness began to appear among the laborers in the plant who fed the bales into the machine and the engineer who supervised its construction and running. Workers engaged in the cutting and trimming of finished bagasse boards were never affected. As soon as it was realized that the dust liberated at the initial stage of manufacture was injurious, measures to suppress it consisted of a water spray and a suction draft applied to the site of its generation. Since these measures were adopted no further cases have occurred. The clinical appearance of the patients suggests an acute inflammatory pulmonary disease with urgent and extreme dyspnea but with little or no febrile reaction. Although bagasse contains 5 to 7 per cent of silica, an amount capable of producing silicosis, the acute pneumonic phase of the illness was unlike any known form of silicosis previously described, and as men who at the final stage of the process were also exposed to a silica-containing dust but never became ill it seemed possible that an allergic factor might be responsible for the disease, that is, that the workers became sensitized to a protein present in the dust of bagasse. Extracts for skin tests were made and it was found that whole bagasse contains an antigen soluble in isotonic solution of sodium chloride to which workers who inhale the dust can become sensitized. The acute phase of bagassosis is possibly an allergic response of the lungs to this antigen with, but more probably without, an infective element. The chronic pathologic process might be due to a form of silicosis which supervenes on the allergic phase during or after the latter's resolution, a response on the part of the lungs to crystalline cellulose or a chronic process of fibrotic nature occurring in tissues edematous from their allergic response to the antigen. Attempts to reproduce the disease in animals have so far failed. The disease should be called bagassosis and not bagasscosis, as it has been

Aortic Size and Accidental Death—As the most constant characteristic of status lymphaticus appeared to be the narrowness of the aorta, Millar and Ross measured 300 consecutive aortas at necropsy to discover whether any connection exists between poor vascular development and frankly accidental death,

that is, from causes which in themselves could not be of sufficient power to produce death in a normal subject. The measurements were studied in relation to age, body weight, height and sex. The mean size of the aorta, corrected for these four variants, of patients dying from accident is significantly lower. Evidence shows that this difference is due, not to dilatation of the aorta in disease, but to developmental hypoplasia of the arterial system in the fatal accident group. This hypoplasia is regarded as connected, probably indirectly with liability to accident. Therefore arterial hypoplasia may be the most reliable guide to the existence of so-called status lymphaticus. In this sense status lymphaticus is regarded as an entity and one to which importance should be attached as a factor in sudden and unexpected death.

Vitamin A Deficiency—The Frober Faybor biophotometer test was used by Dormer and Gibson to determine the vitamin A deficiency in 92 apparently normal healthy young adults (university students), 86 tuberculosis sanatorium inmates (on a diet with an adequate amount of vitamin A for normal requirements), 10 persons suffering from diabetes and that of persons with a vitamin A deficiency after taking various preparations containing vitamin A. Of the first group the curve of 73 per cent was normal, of 16 per cent borderline and of 11 per cent subnormal. The respective figures for the tuberculous group were 43, 27 and 30 per cent. The curves of the 10 diabetic patients were all subnormal. All the subnormal curves of the college students could be explained by food fads or an inadequate intake of vitamin A. In the tuberculous group the deficiency was probably due to excessive metabolism and inefficient absorption. All patients whose vitamin A content had been raised felt better subjectively. The biophotometric reading of tuberculous persons cannot always be improved beyond the borderline, a maintenance dose must be given. Also in spite of large doses of concentrated vitamin A the curves of none of the diabetic patients ever reached normal levels. The metabolism (from absorption to transformation in the retina) of vitamin A is apparently interfered with in diabetes. Of the various vitamin A preparations used a sample of crude cod liver oil with a vitamin A content of 1,483 international units per gram appeared to have no effect in improving the biophotometric curve, but concentrates gave good results.

Celothelioma of Atrioventricular Node—Mahaim's patient acquired pulmonary tuberculosis when she was 22. The following year there developed abdominal symptoms caused by an ovarian tumor which was considered inoperable. Necropsy disclosed the ulcerative type of pulmonary tuberculosis and epithelioma of the right ovary. There were no metastases in the internal organs. There was a tumor of the atrioventricular node which was identified as a celothelioma. This type of tumor was first described by Monckeberg as a lymphoangioendothelioma. In reality the tumor is of embryonal origin. It develops from the epicardic celothelial cells (cover cells). The literature contains reports of only 5 similar cases. A review of the 4 cases reported respectively by Armstrong Monckeberg, Lloyd, Perry and Rogers, and Resek is presented.

- New Method of Determining Chloride Content in Blood Corpuscles M Duboux et C Tschappat—p 338

Respiration and Sickness at High Altitudes—Lenggenhager's extensive studies furnish arguments against the theory of carbon dioxide or hydrogen ion as regulators of respiration. Since carbon dioxide is the terminal product of combustion, its accumulation, according to the law of mass effect, must inhibit the utilization of oxygen. For this reason respiration in a given volume of air is possible longer when carbon dioxide is absorbed. Oxygen consumption is reduced when, in the presence of the breathing of air, carbon dioxide is accumulated. If there is an oversupply of oxygen in the blood, a high carbon dioxide content is tolerated. In the presence of deficient oxygen supply a less than normal carbon dioxide content is tolerated. If carbon dioxide had a direct stimulating effect on the respiratory center the respiratory volume would have to remain the same in the presence of various oxygen containing gas mixtures that have a constant carbon dioxide content, this, however is not the case. The alveolar carbon dioxide is noticeably higher in the presence of high than of low blood oxygen. The consumption of oxygen is made more difficult not only by carbon dioxide but also by severe acidosis (diabetic coma, acid intoxication and uremic coma). This could be a direct action of the hydrogen ion or an indirect effect of the metabolic carbon dioxide. On the other hand, every alkalosis improves the oxygen consumption either because of a reduction of the hydrogen ions or because of a decrease in carbon dioxide. It is possible that this factor explains the slight metabolic increase at moderately high altitudes. If the body loses too much carbon dioxide on account of hyperventilation, the tissues, particularly those of the brain, are gradually damaged by the resulting alkalosis. The respiratory center becomes less responsive. Anesthetized animals can be killed by passive hyperventilation. Respiration becomes deeper with increasing oxygen depletion if carbon dioxide is added to keep its content constant. The former explanation of the increase in the respiratory volume in oxygen deficient air by way of the formation of hypoxemic acids in the respiratory center or in the peripheral "chemo-

ceptors" cannot be correct. Bohr's law which applies to blood in vitro plays a subordinate role in living tissues. High altitude sickness is probably caused not so much by oxygen deficiency as by the acute alkalosis. This view was supported by experiments in a low pressure chamber. At 9,000 meters addition of carbon dioxide to the inspiratory air completely counteracted the threatening symptoms. After alkalosis has acted on the brain tissues for a while the cerebral functions become more difficult. High altitude sickness presents the cumulative effect of impairment of the cerebral functions by alkalosis and oxygen deficiency.

Paget's Osteitis Deformans and Hyperthyroidism—According to Lyon the thyroid hormone exerts an important influence on the skeletal system. Hyperthyroidism is almost regularly accompanied by progressive osteoclastic bone atrophy. Osteitis deformans of Paget is less often encountered in hyperthyroidism. When the two disorders occur the question arises whether this association is accidental or whether there exists a causal connection. The author reports a case in which hyperthyroidism had existed for years. Paget's osteitis deformans had been demonstrated in the pelvis since 1934 and osteoporosis of the vertebral column in 1939. Paget's osteitis deformans is an osteoclastic bone atrophy with mass production of inferior bone. Its active stage is characterized by increased serum phosphatase, positive calcium balance, increase in the blood cholesterol and a hypovitaminosis, which readily yields to vitamin administration. A constitutional predisposition to osteoclastic bone atrophy is the underlying cause of Paget's osteitis deformans, and this predisposition is made manifest by a hypovitaminosis of various origins. Hyperthyroidism was responsible in the author's case. The therapy aims to transform the disease into the stage of remission. The cause of the vitamin A deficiency must first be ascertained and counteracted. In the reported case the hyperthyroidism was treated by roentgen irradiation. Prolonged and intensive treatment with vitamin A is indicated in all cases.

Electrocardiographic Records Under Influence of Digitalis—Sellmer studied the effects of digitalis on electrocardiograms of 60 patients with and without heart disease. His investigations concerned the minimal dose which produces digitalis effects, the time of its first appearance and the persistence of electrocardiographic changes. To obtain exact data, the majority of patients were subjected daily to electrocardiographic examinations and sometimes hourly tests were made. The quantities of digitalis administered and the duration of the medication varied greatly. Extremely small as well as large doses (0.1 to 64 Gm) were administered for from one to forty-two days. Typical digitalis changes such as the lowering of the ST and the flattening of the T wave were observed after extremely small doses (0.1 to 0.5 Gm) and usually in the course of the first three days, in exceptional cases after from one to several hours. The changes persisted for from five to forty days, the average time was two to three weeks. There was no essential difference between the reaction of the diseased and the healthy heart. The customary digitalis effects were observed also in the healthy heart. The individual differences in reaction were pronounced and must be ascribed to disparity in the susceptibility to digitalis.

- Postthoracoplasty Cavitary Gangrene R Consighiere and O A Vaccarezza—p 433

Serum Precipitation by Sulfuric Acid—Tabanera treats 0.2 cc of human serum with 3 cc of an 8½ per cent solution of sulfuric acid in twice distilled water. The blood is taken when the patient is fasting and with a dry sterilized syringe. The serum must not show signs of hemolysis. The test tubes are kept at a temperature of from 18 to 20 C and the results can be read at the end of twenty-four hours. Normally, formation of a precipitate is observed (negative reaction). In certain morbid conditions such as tuberculosis, particularly with an intestinal localization, no precipitate is formed within a fixed time (positive reaction). In order to learn the nature of the precipitate normally obtained, color reactions were made to identify the amino acids. Other factors investigated were the isoelectric point of the precipitate, its relation to nitrogen its protein fractions and the protective action of human serum on animal serum and other substances. The precipitate produces the positive reaction of amino acids, and the relation between its nitrogen and dry extract corresponds to the conversion of nitrogen to protein (6.25). Electrodialyzed serum is not precipitable with sulfuric acid. The pseudoglobulin of normal serum does not prevent precipitation, whereas the pseudoglobulin of serums with positive reaction have a great protective power and the increase of its quantity is proved by protein fractionation. The absence of precipitation (positive reaction) can be explained by the increase of the pseudoglobulin fraction or by the presence of a protective substance in it. The positive human serum protects the normal serum of man and of various animals the same as a hydroalcoholic solution of casein.

Roentgenologic Examination of Thorax with Caudal and Cranial Direction of Rays—Enquin studied the value of the x-ray exploration of the thorax with cranial and caudal projection of the rays. These angles of projection permit the visualization in frontal exposure and are free from bony obstruction to the apical and subapical pulmonary fields, the two lobes, particularly the left one, the anterior and posterior slopes of the diaphragm, the apex and the lower border of the heart. The pictures obtained with these projections differ greatly from those obtained with standard angles of projection. The theoretical foundations and the diagnostic value of these differences are discussed. The diagnostic value of the exposures described is often superior to that of tomography. These angles of projection are of particular importance for the examination of apical and subapical lesions and for the study of incisional and juxtainscissural processes and for the diagnosis of cavities.

Perforation of Tuberculous Ulcers of Intestine—Lamberti reports that necropsies on 464 patients with pulmonary tuberculosis revealed ulcerative intestinal lesions in 258 (55.6 per cent). A perforation of the intestine was found in 9 cases in 1.93 per cent of those with pulmonary tuberculosis and in 3.48 per cent of those with intestinal tuberculosis. The perforation was located in the ileum in 4 cases in the ileum and appendix in 1 case and in the appendix in the 4 remaining cases. The clinical diagnosis was established in 7 cases which presented the symptomatology of a generalized peritonitis.

- *Coconut Water as a Culture Medium C Picado T—p 960

Coconut Water as a Culture Medium—Picado T directs attention to the value of coconut water as a culture medium. The war, with its interruption of transportation has prevented many small laboratories from obtaining their usual supplies of culture mediums. San Juan de Dios Hospital has employed coconut water as a culture medium for the past twenty-five years. Coconut water contains magnesium nitrogen phosphorus, sodium, potassium sulfur, zinc iron sucrose, calcium aluminum and chlorine and closely resembles Raulin's liquid. The natural acid coconut water sterilized by boiling used as liquid or jelled serves as an excellent medium for the growth of fungi of human and plant mycoses for industrial yeasts for plant bacteria, for acidophilus bacilli for the germination of orchids and for the development of fruit fly larvae. Bacteria pathogenic to man and animals require that the coconut water be alkalinized. The economy of the medium in tropical countries is obvious.

- *Staining Treponema Simple Rapid and Reliable Technique T G Perrin—p 404

- *Digitalis Lanata Clinical Effects S Aceves—p 410

Staining Treponema—Dark field examination of Treponema, according to Perrin, has the disadvantage that the material cannot be preserved. With his method it is possible to stain Treponema either in fresh or in dried preparations. The reagent is prepared with 10 cc of a 10 per cent formaldehyde solution, 4 cc of Ziehl's fuchsin and 1 cc of acetic acid. Fresh preparations may be stained with or without previous fixation. The slide is stained for two minutes if heat is used and for six minutes if heat is not used. It is then washed in distilled water, dried and observed under the oil immersion lens. Dried preparations are covered with a slide having a fine layer of balsam or of oil of cedar. The reagent can be used in staining nuclei and tissue sections. The author employed this technique for staining bacteria in serous exudate of a syphilitic chancre, in pus of maxillofacial polyarthritis and in the lymph of dyschromic skin in experimental pinto. The technique proved to be rapid and reliable. Treponema stains uniformly and is clearly differentiated.

Digitalis Lanata—Aceves treated 25 patients with decompensated heart disease by rest in bed and diet followed by administration of the glucosides of Digitalis lanata (digitalin). The drug was given intravenously or by mouth in a dose slightly larger than that of Digitalis purpurea. The effect of Digitalis lanata on the heart is similar to that of Digitalis purpurea. The drug corrects the insufficiency by increasing the contractility of the myocardium. The effects are rapid when the drug is administered intravenously. Adequate therapeutic doses are well tolerated for a long period. Larger doses of the drug may cause gastrointestinal and nervous disorders and changes in the electrocardiogram characteristic of digitalis intoxication.

Acute Perforations of Malignant Gastric Tumors—The rarity of acute perforations of malignant gastric tumors induced Garcia Barón to report 3 such cases. The first patient had a primary carcinoma without a history of gastric disturbances. The first symptom was the perforation. The second patient had apparently an ulcer carcinoma. The third had a

sarcoma with a history of hyperacidity, of a subacute perforation leading to a subphrenic abscess and an apparent surgical cure which was followed within a few months by the development of a stenosing tumor, the sarcomatous nature of which was discovered by biopsy. Diagnosis of perforation was made in all cases before the operation, but in none was it recognized as cancerous. Aird reported in the *British Journal of Surgery* in 1935 79 cases culled from the literature. At the author's hospital there were four hundred ulcer perforations in twelve years but only three cancer perforations. The male sex was predominant, 75 per cent of the 79 patients in the world literature and all 3 of the author's patients being men. Surgical treatment is indicated, for without it the patient is lost. The surgical mortality is approximately 68 per cent. The cancers are usually prepyloric. The intervention should be limited in the majority of cases to simple closure of the perforation, which in some cases is combined with a gastroenterostomy. Roentgenologic examination is valuable in the diagnosis because spontaneous pneumoperitoneum is often a pathognomonic sign of perforation.

Constitution and Pellagra—Díaz-Rubio points out that when the etiology of pellagra is considered the pellagrigenic diet generally receives most attention. Poor hygiene, physical and mental overwork, the concurrence of infections and intoxications and the seasonal factor are usually regarded as contributory factors but a predisposition is not considered. The author cites factors which indicate the presence of a special predisposition or resistance for or against pellagra, the most important being existence of a familial pellagra, age, pregnancy and menopause, clinical multiformity, failure of the disease to develop in spite of a prolonged pellagrigenic diet, cures of spontaneous cure in spite of the diet and failure of an early antipellagral diet in other cases. The basis of the predisposition is to be found in the endocrine system and in the constitutional habitus. The pellagral symptomatology is severe in asthenic and hypoplastic persons and is comparatively mild in persons with a pyknic build. The endocrine formula manifested by an increased functional tonus of thyroid and pancreas and by a deficient function of the anterior pituitary and of the adrenals and by a follicular predominance create a considerable susceptibility to pellagra, whereas in persons with the opposite endocrine formula the predisposition to pellagra is slight. The function of the adrenals seems to be the most important one among the endocrine elements that play a part in the pathogenesis of pellagra.

Selective Staining of Rickettsias—Gracín Carido points out that the microscopic examination of materials containing rickettsias presents difficulties because of the extreme smallness of these parasites and because a differential stain is hard to obtain particularly when the vitelline sac of the chicken embryo is used for the culture of rickettsias in the preparation of the antityphus vaccine. The following method was developed by the author: 1. Make a thin smear on a slide and let it dry well. 2. Without previous fixation cover the smear with xylene for three minutes. 3. Drain off the xylene and wash twice with 90 per cent alcohol. 4. Wash with water. 5. Cover the preparation for three minutes with a saturated solution of potassium bichromate. 6. Wash thoroughly with water. 7. Cover with a 10 per cent Giemsa solution from ten to twenty minutes. Wash with water, dry and examine. The preliminary treatment with xylene and bichromate stains the rickettsias intense red or dark blue on a colorless or slightly stained background. In the thicker parts of the preparation the micrometer screw makes it possible to see the well stained rickettsias in different planes. This method of staining clearly differentiates the rickettsias from cell and egg protein remnants.

*Acute Leukemia in Adults O. Montoro—p. 345

Acute Leukemia in Adults—Montoro points out that acute leukemia differs from chronic leukemia in its clinical and hematologic manifestations. The disease is rapidly fatal, its etiology unknown and its onset sudden. It is more frequent in children than in adults, in men than in women and during the menopause than at any other age for adult women. It is excep-

tionally rare in old persons. Pregnancy, abortion, infections and trauma to the spleen or bones can act as determining factors in the development of the disease, which may manifest itself in asthenic and febrile, agranulocytic, hemorrhagic, typhoid, neoplastic and comatose types and as typical acute leukemia. In all types, however, the number of immature cells is increased although the peculiar type depends on the predominant type of immature cells. From the point of view of the predominant type of immature cells, acute leukemia in adults corresponds to any of the six different types, namely: (1) the hemocytoblastic, (2) the myeloblastic, (3) the paramyeloblastic, (4) the myelocytic, (5) the lymphoblastic and (6) the monoblastic. In all forms of acute leukemia the hemogram corresponds to any of the following changes in the blood or in the hemopoietic organs: (1) an acute increase of immature leukocytes, up to 85 per cent, (2) a subacute increase of immature leukocytes, (3) acute diminution of platelets, (4) normal or delayed coagulation time and prolonged time of hemorrhage, (5) resistant anemia of the normocytic or microcytic type, of rapid development with globular values which vary from 1 to 12, (6) acute hyperplasia of the hemopoietic organs with predominance of myeloblastic, lymphoblastic and monocytic cells in the various forms of acute myelosis, acute lymphatic leukemia and acute monocytic leukemia. The oxidase reaction is of value in differentiating monoblasts and myeloblasts by showing certain characteristics of the monoblastic and myeloblastic granulations during the reaction. The presence of Auer's bodies in the hemogram is pathognomonic of the myeloblastic type of leukemia. The disease is fatal in one to three months. Treatment consists in the massive administration of liver, blood transfusions, arsenic preparations and symptomatic measures.

Infection Factor in Cholera in Infants Sulfanilamide Therapy J. Muñoz-Turnbull—p. 201

Sulfanilamide Therapy in Cholera—Muñoz-Turnbull believes that infection is the predominant factor in cholera of infants and that dehydration and malnutrition are secondary. He treated successfully 5 cases with sulfanilamide. The drug was administered by mouth in doses of from 0.1 to 0.2 Gm. every five hours up to a daily dose of from 0.4 or 0.8 Gm. for two consecutive days, after which a dose of 0.1 Gm. was given every five hours up to a daily dose of 0.4 Gm. for two more days. The patients also were given intravenous injections of 140 cc. of a mixture of equal parts of Hartmann's solution and of 20 per cent dextrose solution and 10 per cent dextrose solution by mouth. All of the patients recovered.

Corpus Luteum Action of Adrenal Cortex Extract on Mucosa of Uterus O. Neumann—p. 1969

Quantitative Behavior of Estrogenic Substances in Intrauterine Death of Fetus T. Koller and F. Leuthardt—p. 1972

New Breast Pump H. O. Klein—p. 200

Corpus Luteum Action of Adrenal Cortex Extract on Mucosa of Uterus—Neumann cites factors which indicate close relationship between gonads and adrenal cortex. Progesterone action with desoxycorticosterone has been reported by a number of investigators and this is understandable in view of the close chemical relationship between progesterone and desoxycorticosterone. Since animal experiments had succeeded in transforming the uterine mucosa by means of desoxycorticosterone, an attempt was made to do the same in human subjects. Two castrated women were given in the course of fifteen days six doses of estrogenic substance. After their endometrium had been thus prepared they were given for a week daily injections of desoxycorticosterone acetate. The result was the development of the secretory phase of the uterine mucosa. Bleeding set in which resembled menstruation. To produce this transformation of the uterine mucosa approximately 300 mg. of desoxycorticosterone acetate was necessary. These large doses were well tolerated. Although the adrenals do not produce or contain sex hormones, their own hormone so closely resembles progesterone that in large doses it can produce the effects of the corpus luteum hormone.

Book Notices

Occupational Tumors and Allied Diseases By W. C. Hueper M.D. Assistant Director and Principal Pathologist, Warner Institute for Therapeutic Research, New York City. Cloth. Price \$8. Pp. 896. Springfield, Illinois & Baltimore: Charles C. Thomas, 1942.

This volume includes essentially a review of the available medical literature dealing with tumors arising in industry. The author apologizes for the unevenness in the presentation of various aspects, which he feels is due to the fact that the amount of information available regarding each type of tumor varies. Following each section of the work is a bibliography indicating the sources that have been consulted in preparing the material. Obviously such a compilation is useful, since it fills a field not previously covered.

While most of the chapters are well written and conform with accepted views on the subject, the author contradicts himself in some in the evaluation of the statistics and papers which he reviews. In the chapter on arsenic he quotes statistics from England stating that there occurred "during the last five decades a total of seventeen arsenical cancers of the skin, of which four must be regarded as doubtful." This is an incidence of 1 case in three years, surely almost negligible. And yet the author concludes that the statement of Schwartz "that he had not seen a single case of occupational arsenical keratosis or epithelioma among the arsenic workers he examined" shows an "extraordinary immunity of American workers to arsenical malignancy" and that "actual evidence available presents a picture quite different."

The author's statement "that the United States has furnished not only the largest number of frank industrial arsenical cancers during the last ten years but seems to lead all other countries in the number of chronic arsenical dermatoses of occupational origin, according to the data recorded in the literature" is not borne out by the records of the industrial compensation boards. There is not 1 case of industrial arsenical cancer among all the records of the state compensation boards sent to the Section of Dermatoses Investigations of the United States Public Health Service during the last five years. That this is not due to the fact that reporting physicians overlook the skin lesions caused by arsenic exposure is evidenced by the many cases of occupational arsenical dermatitis which are reported.

Another example of faulty evaluation of the literature which might be due to lack of experience can be found on page 764. The majority of the authorities on melanin do not believe that melanin is found in the blood or urine under normal conditions. In discussing the incidence of pigmented epitheliomas among Negroes there must be a careful use of terms and consideration of differential diagnosis. Certainly no one has ever suggested that melanomas are of occupational origin. Besides, an occupational epithelioma in a Negro might very well be pigmented. The book contains other instances of such faulty reasoning.

On the whole, the special character of the book tends to give an exaggerated picture of the frequency of occupational cancers of the skin, since the data thus far available are hardly sufficient on which to make certain the differential diagnosis between occupational and nonoccupational tumors.

You Must Relax: A Practical Method of Reducing the Strains of Modern Living By Edmund Jacobson M.D. New edition. Cloth. Price \$1.75. Pp. 261 with 27 illustrations. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1942.

In the revised edition improvements have been made in style, and in the illustrations a shapely young woman replaces an indifferent looking man, in addition are a new chapter on war nerves and two new chapters on sleep, also an index. In the new material the author states that the basal metabolic rate is below normal when one consumes less oxygen and gives off more carbon dioxide. He also challenges the view that motility during sleep is a normal phenomenon. Essentially the author's thesis is unchanged: there is a difference between "ordinary and cultivated relaxation." "The additional relaxation is slight indeed. Yet this slight advance is precisely what is needed." Although the volume is intended for "persons who lack opportunity for medical consultation on matters of tension

and relaxation, the patient without help from the physician "is often mistaken as to whether he has been successful and consequently may fall into wrong habits of tension. But where aside from Dr. Jacobson is the physician who can help him?" The criticism made in the review of the first edition of this book (*THE JOURNAL*, July 21, 1934, p. 210) that "the book would be of great practical value if the author had already succeeded in 'selling' his theory and practice of progressive relaxation to the medical profession and now wished to tell the lay public what it was all about" is justified more than ever by the failure of the author to secure general acceptance for the detail of his therapeutic method in the intervening eight years.

Introduction to the Psychoanalytic Theory of the Libido By Richard Sterba M.D. Nervous and Mental Disease Monographs No. 68. Board. Price \$2. Pp. 81. New York: Nervous and Mental Disease Monographs, 1942.

This monograph represents a condensed, simplified review of Freud's theory of instincts. The criticism has been voiced that it is oversimplified and that further elaboration of Freud's original theories, which are quite generally accepted by progressive psychoanalysts, should have been included in the presentation. The title of the book, however, indicates that only an introduction to the study of instincts is intended. It is certainly true as the author states in the preface, that "psychoanalysis, successful as a therapy and increasingly accepted by science as it is, has nevertheless to face a real danger nowadays. An attempt is being made by some analysts to teach and practice psychoanalysis without acknowledging the fundamentals of Freud's theory of instincts. In their papers they try to deal with the problems of the mind in general and of neurosis in particular, without taking into account the instinctual forces, those gigantic powers discovered by Freud, which operate behind the mental manifestations of mankind. For these instinctual forces they substitute cultural influences in order to explain neuroses, and they regard themselves as being advanced in comparison with Freud and his theory of instincts. The public is impressed. Once more they spare the polite world the recognition of the 'all powerful melody of the instinctual forces,' just as did Adler and Jung thirty years ago. It seems timely, therefore, to recapitulate Freud's findings in the domain of the instincts, and particularly of the sexual instinct." This book is instructive and easy to read. Dr. Sterba expresses in simple understandable language a sound fundamental condensation of acceptable, and for the most part accepted, theory of the libido.

Personality and Sexuality of the Physically Handicapped Woman By Carney Landis Ph.D. Associate Professor of Psychology, Columbia University, New York, and M. Marjorie Bolles Ph.D. Research Fellow, Psychiatric Institute and Hospital, New York. Cloth. Price \$3. Pp. 171. New York & London: Paul B. Hoeber, Inc., 1942.

In this book the authors report a study of the psychosexual development of 100 physically handicapped women. The subjects were 25 women with an orthopedic disability, 25 with spastic paralysis, 25 with chronic heart disease and 25 who had been diagnosed as epileptic. The information was obtained by means of a controlled interview, a medical history and the Rorschach test. On the basis of this information the authors concluded that personality manifestations and disturbances do not correlate with specific physical disturbances. They found that any persistent physical handicap resulted in hyposexuality and psychologic immaturity. They also concluded that in most cases psychosexuality was not an important component in personality formation. Their findings showed that no existent psychologic or psychiatric theory could be used to explain the growth of personality and sexuality of the physically handicapped woman. They therefore concluded that the reaction tendencies which become formalized in childhood determine the later personality. A temporary physical defect causes the same type of reaction as a permanent defect. In those who recover from physical defects, personality and sexuality may develop normally. For example, personality deviations and psychosexual immaturity are found in normal women who have had frequent illnesses during childhood.

The book is well written and the material is clearly presented. The details of the findings and the various scales which were used are given in the appendix. The distribution of case

materials is not adequate, however, for the sweeping conclusions. No details are given by the authors regarding the distribution of the severity of the physical defects. One might infer that all the cardiac cases represented mild heart conditions or possibly individuals with very serious cardiac conditions. The authors state that the women were intensely interested in the project and volunteered their service and therefore were honest, and their answers fully represented their attitudes. This is only problematic, however, for every psychiatrist knows how difficult it is to obtain the true attitudes of a patient in spite of his professed willingness to tell everything about himself.

Effects of Alcohol on the Individual. A Critical Exposition of Present Knowledge. Volume I. Alcohol Addiction and Chronic Alcoholism. Edited on Behalf of the Scientific Committee of the Research Council on Problems of Alcohol by F. M. Jellinek. Cloth. Price \$4. Pp. 336. New Haven: Yale University Press; London: Oxford University Press, 1942.

This is the first volume of three, outlined in the introduction, proposing the independent and unbiased study of the medical and sociological aspects of alcohol. The present volume is given over chiefly to a discussion of the clinical aspects of the problem of alcohol and the clinical effects of its prolonged ingestion. It is divided into two parts. Part I contains chapters on alcohol addiction and its treatment by Karl Bowman and E. M. Jellinek, and on alcoholic mental disorders by the same authors. These are excellent and comprehensive reviews of the subjects. Probably nowhere in the literature is the subject of alcoholic mental disorders so clearly presented as in this chapter. Part II contains chapters on vitamin deficiencies in chronic alcoholism by Norman Jolliffe, on alcoholic encephalopathies and nutrition by Norman Jolliffe, Herman Wortis and Martin Sterne on Marchiafava's disease by Giorgio Lolli and on cirrhosis of the liver by Norman Jolliffe and E. M. Jellinek. While this section does not make such easy reading as part I, owing to the diversity of the subjects and the differences in the style of its writers, it is well up to standard. To devote an entire chapter to so rare and obscure an entity as Marchiafava's disease seems a little out of proportion but this is a minor point of criticism. The bibliography is exhaustive and constitutes no small part of the value of the book. The authors are to be congratulated on their objective point of view, and it is only in rare instances that any personal scientific prejudice has shown itself. Both the scientific committee and the authors are to be congratulated on producing a volume which may well serve students of the problems of alcohol as an authoritative work of reference.

Lymph Node Metastases. Incidence and Surgical Treatment in Neoplastic Disease. By Grantley Walder Taylor, M.D., M.B., F.A.C.S., Instructor in Surgery, Harvard Medical School, Boston; and Ira Theodore Nathan, M.D., M.S., Instructor in Surgery, Harvard Medical School. With a foreword by Shields Warren, M.D., Assistant Professor of Pathology, Harvard Medical School. Cloth. Price \$8. Pp. 198. With 61 illustrations. New York: Toronto & London: Oxford University Press, 1942.

This book presents the results of a study of lymph node metastasis in cancer and its treatment. The first part describes the anatomy of the lymphatic drainage of the neck, the axilla and arm, the groin, the pelvis and abdomen, and the thorax. The second part deals with regional lymph node metastasis and is based on an analysis of some 5,500 cases, almost all of carcinoma, treated in the Massachusetts General, the Huntington Memorial and the Pondville hospitals. The cases in each part of the body have been studied with respect to secondary lymph node involvement, which occurred in about half of the cases observed, roughly averaged. Answers are recorded to questions like these: The location, duration, size, grade and control of the primary carcinoma? The particular nodes involved? The time and curability of lymph node metastases? Details are summarized clearly in the text and in one hundred and seven tables. In the third part the surgical removal of lymph node metastases is considered. Dissections of the cervical, axillary and inguinal lymph nodes and other operative procedures are described. At the end of each chapter are listed references to the publications discussed in the text. The drawings illustrate nicely lymph nodes, lymphatic drainage systems and dissections. The indexes, subject and author, seem to be complete. The book is the outcome of extensive and thorough work. It will be of interest and aid to all who are concerned with the diagnosis and treatment of cancer, to the literature of which it is an important and substantial addition.

Chronic Pulmonary Disease in South Wales Coalminers. I. Medical Studies. A Report by the Committee on Industrial Pulmonary Disease. II. Medical Survey. By P. D. Arey Hart and E. A. Ashall, with contributions by D. Hicks and R. Yates. C. Pathological Report. By T. H. Belt, with assistance from A. A. Ferri. Medical Research Council Special Report Series No. 217. Boards. Price 10s. 6d. Pp. 222. With illustrations. London: His Majesty's Stationery Office, 1942.

This is an excellent report representing clinical and pathologic investigation into the unusual incidence of certified silicosis in South Wales. Students of the subject will be interested in the use of the new term "reticulation" in the classification of x-ray patterns. There is sound justification for this use since the modified form of silicosis with which these observers dealt definitely differs from others produced by most of the mineral mixtures. Belt makes out an excellent case for this terminology pathologically as well. In order to grant compensation in certain cases in which apparently disablement exists without x-ray evidence of nodulation, all these cases are classified under the heading "the pneumoconiosis of coal miners." The whole method of presentation is most impressive. Cuts are good and the argument is clear and forceful. Presumably, final judgment on the conclusions reached will need to await the provision of data on conditions of exposure, which evidently will be the subject of a subsequent report.

Civilian Health in Wartime. By Francis R. McNeal, M.D., Associate Professor of Medicine, Harvard Medical School, Massachusetts General Hospital, Boston. Cloth. Price \$2.50. Pp. 328. Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1942.

This book is easy to read and gives sound information on the subject of civilian health. The chapters on nutrition and diet make excellent reading and give dependable information. Of special interest is the statement concerning concentrated diets, which the public is led to believe make the "German armies invincible." The author states: "It is notable that German soldiers immediately ransack the restaurants and borders of newly occupied territory with an avidity which has greatly impressed American correspondents." Especially pertinent at this time is the chapter entitled "About Our Doctors and Nurses." The list at the end of the book for additional reading is worth while.

Group Differences in Urban Fertility. A Study Derived from the National Health Survey. By Clyde A. Kiser. Cloth. Price \$2.50. Pp. 284. With 70 illustrations. Baltimore: Williams & Wilkins Company, 1942.

Interest in population facts and population trends has reached a peak in recent years. Most of the facts of population distribution now are quite accurately determined by the decennial census, the projection of probable population trends into the future and the interpretation of their meanings are being subjected to searching study by a considerable group of qualified investigators. This book deals primarily with the fertility rate in urban areas and the various factors which affect it, such as occupation, educational attainment and family income. The conclusions are not particularly astonishing to any one who has been familiar with recent investigations in the field. It has been well known for some time, for example, that large urban populations in this country do not reproduce themselves. Nevertheless this book represents a careful documentation and interpretation by one of the leading workers in the field. Sound fundamental information of this nature is necessary if work in the social field is ever to reach the stature of a true science.

Manual of War Time Hygiene. By Dean Franklin Smithey, M.D., Professor of Hygiene and Preventive Medicine in Cornell University, New York; and Adrian Gordon Gould, M.B., M.D., Attending Physician and Assistant Professor of Hygiene and Preventive Medicine in Cornell University. Supplement to A College Textbook of Hygiene. Paper. Price \$1. Pp. 56. With 11 illustrations. New York: Macmillan Company, 1942.

This small book is intended as a supplement to "A College Textbook of Hygiene" by the same authors. It is divided into three parts, on military hygiene, civilian defense and wartime first aid. The authors believe that in wartime the college student's work in hygiene must be considerably reoriented. Personal hygiene will have increased importance because the student is fitting himself for the health of men in the armed forces. Community hygiene must, in these wartimes, deal largely with problems of field sanitation and military organization for combating infectious disease, wounds and gassing. This booklet can be recommended as a supplement to the author's college textbook on hygiene.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

HYPNOTISM AS THERAPEUTIC PROCEDURE

To the Editor—Will you please inform me about the present status of hypnotism as a therapeutic procedure? Is there any actual danger in its indiscriminate use by laymen? Please suggest bibliographic references on the subject.

M D Puerto Rico

ANSWER—Hypnotism suffered the fate of other methods of therapy which have become associated with charlatanism and which have been hailed with undue enthusiasm. It fell into disrepute with physicians because, unlike psychoanalysis, it deals largely with symptoms rather than causes. It is essentially for this reason that this valuable therapeutic technique may be dangerous in the hands of the public, for symptoms may be created or intensified without a proper knowledge of the underlying pathologic condition. All physicians are aware of the power of suggestion, and in the state of hypnosis conscious resistance is reduced to a minimum. The patient is put in a condition of heightened suggestibility and he accepts suggestions without criticism.

One of the greatest obstacles in psychotherapy is to get the patient to accept therapeutic suggestions consciously. Under hypnosis it is possible to implant therapeutic ideas on the "sub-conscious" and to have them take effect when endless numbers of suggestions given in the waking state would be ignored or even actively resisted. Also under hypnosis former dissociated experiences and amnesic material can be rendered available for reassociation and reorganization. Of course, like any form of psychotherapy, the results of hypnosis are individually limited, and they vary in degree and variety with every subject, depending on the innate endowment of the patient.

The mechanism of normal sleep and that of hypnosis are the same. Normal sleep, like hypnosis, is a condition of dissociation. In fact, the physician can frequently influence by suggestion a normally sleeping person and transport him into hypnosis without awakening him. All persons are in a condition of hypnosis, or dissociation, during the course of normal sleep and confuse dream thoughts with actual occurrences. It is for this reason that sleep is advantageous for the application of suggestion.

Some of the compulsion neuroses and the hallucinations of the psychoses may be explained on heightened suggestibility. Spontaneous hypnosis has been known to occur and to be mistaken for absentmindedness, spontaneous trance, the loss of identity or the amnesia found in the hysteroid epileptic. Just as these psychopathologic symptoms have occurred, so they may be removed by the same process.

The physician who wishes to use hypnosis must know how to convince his patient that he is capable of doing so, and he must be able more or less to induce an enthusiasm for this form of treatment. Thus the practitioner must either be convinced himself or, failing this, possess a dramatic personality in order to convince others. Everything which fills a person with enthusiasm gains control over his brain activity, easily conquers all the contrary impressions and leads the person into receptivity. Therefore the hypnotizability of a person increases with his enthusiasm and with his confidence as well as with the enthusiasm and former success of the practitioner.

As will be evident from the following bibliography, hypnosis has a definite place in psychotherapy. It is not a mysterious art, but a scientific technique.

ROENTGENOGRAPHY IN DIAGNOSIS OF AORTITIS— POSITIVE WASSERMANN TEST IN LATE SYPHILIS

To the Editor—A man aged 50, 6 feet 2 inches (188 cm) tall, weight 180 pounds (82 Kg) had been active and in excellent health. In February 1940 he fractured a fibula in an accident. While in a hospital for treatment of the fracture he was found through routine blood examination to have a strongly positive Wassermann reaction. He did not remember ever having had primary or secondary lesions of syphilis. Careful physical and neurologic examinations with syphilis in mind disclosed nothing but perhaps some increased dullness across the aortic area. The spinal fluid was not examined. The report on the x-ray examination of the cardiac area was: "Transverse diameter of heart 13.3 cm, aorta 8.2 cm, dilatation of transverse arch of aorta typical of syphilitic aortitis." Two other Wassermann tests were done by different laboratories and they too were reported strongly positive. It was explained to the patient that he had a syphilitic infection of perhaps twenty years duration which although latent had damaged his aorta and that he now had an early aneurysm. Treatment was started immediately by weekly injections of a bismuth compound of which he received fifteen followed by twelve of nearsphenamine in 0.3 Gm doses which was increased to 0.45 Gm as it was well tolerated. This was followed by twenty-three injections of the bismuth compound after which came ten injections of nearsphenamine beginning with 0.45 Gm increased to 0.6 Gm, as the Wassermann reaction was still strongly positive. He then was given fifteen injections of the bismuth compound followed by fifteen injections of bismarsen. All these injections were given at weekly intervals. Thus in one year and eleven months of continuous treatment he received fifty-three injections of bismuth preparations and thirty-seven of arsenicals. The Wassermann reaction was strongly positive. He was given a six months rest for business reasons; he still felt well and had no symptoms at all attributable to his heart. He played golf and hunted and he was in perfect health. This year he has received a bismuth compound intramuscularly at intervals of two weeks. He still feels well and still has strongly positive Wassermann and Kahn reactions. He has received regularly every six months an x-ray examination with the same technique as the first examination. At the end of one year's treatment the report was: "No further dilatation of any part of aortic arch. Heart not enlarged. Successful arrest of syphilitic aortitis." At the end of 1942 the report was: "Transverse diameter of heart 14 cm, aorta 8.8 cm, the difference in measurements from 1940 of questionable significance. Impression: relatively unchanged aortitis over period February 1940 to November 1942." The man is in excellent health except that he still has a positive Wassermann and Kahn reaction. Treatment has not changed the size of his aorta. What should be the further treatment?

M D Georgia

ANSWER—The diagnosis of uncomplicated syphilitic aortitis cannot be made on the basis of posteroanterior teleroentgenography alone. An aortic width of 8.2 cm demonstrated by this x-ray technique is not at all uncommon in nonsyphilitic persons 50 years of age or older. For a discussion of the importance of this point see Kemp, J E, and Cochems, K D. Studies in Cardiovascular Syphilis. I. Teleroentgenography in the Diagnosis of Early Syphilitic Aortitis. A Comparison of Findings in 1,000 Syphilitic and 600 Non-Syphilitic Individuals, *Am Heart J* 13: 297 (March) 1937. Arteriosclerosis and hypertension, either one alone or in combination will produce this degree of widening of the supracardiac shadow, and indeed as much as this may be expected as a physiologic process in a certain proportion of elderly persons.

The diagnosis of uncomplicated aortitis cannot be made in any case on the basis of x-ray findings alone, whether the teleroentgenographic technique includes, as in this instance, only posteroanterior roentgenography or the more desirable fluoroscopic and teleroentgenographic examination in the left anterior oblique position. The latter permits a demonstration of the silhouette of the aorta and is a much more accurate measure of aortic dilatation and its localization as contrasted with the aortic elongation and tortuosity accompanying arteriosclerosis or advancing age than is the technique employed in this case. Essential for the diagnosis of syphilitic aortitis, in addition to x-ray evidence of aortic widening, is the presence of symptoms, physical signs or both. The most important physical signs, in the absence of hypertension, are a rough systolic murmur in the aortic area and a tympanic bell-like tambour accentuation of the second aortic sound. In this case it is distinctly stated that the physical findings were normal.

The term "aneurysm" is certainly an unjustifiable diagnosis in this case unless actual sacculcation has been demonstrated. This does not appear to have been done.

This patient has had enough antisyphilitic treatment. In the absence of symptoms or physical signs of cardiovascular disease, the positive serologic test in the blood may be disregarded. Seroresistance in this situation, i.e. late syphilis, is the rule rather than the exception and is not of importance in prognosis.

GREEN DISCOLORATION BETWEEN TOES

To the Editor—A girl aged 18 has a green pigment occurring between the layers of skin between the toes of both feet. There is no irritation of the skin and no scaling or any other pathologic condition noted. The family history is negative and the patient's past history is negative except that she has sinusitis. For this she has been using only salt water in the nose and has been taking no drugs. The urine is negative for albumin and sugar, and the Wassermann reaction is negative. This condition has been coming on since August 1942, and I should like to know what could possibly be the cause. No local applications of any sort, including talcum powder have been used and there is no sign of dye on her hose or in her shoes.

Robert S. McCeney, M.D., Laurel Md

ANSWER—Except for the temporary green color seen during the absorption of hemorrhage into or beneath the skin, green discoloration of the skin is seldom seen. There are few references to it in the literature. The principal possibilities are (1) dye from the stockings or shoes, (2) dye applied by the patient with intent to deceive, (3) color produced by the growth of some bacterium or fungus or (4) excretion of copper in the sweat.

1 The statement in the query that no dye has been found on the stockings or shoes makes this explanation unlikely. Stains between the toes without any discoloration on the dorsum of the feet or on the soles would be possible only if the dye was easily washed off and the patient carefully refrained from washing between the toes.

2 In all cases difficult of explanation, this possibility should be carefully considered.

3 Unless there is a chance that copper has been absorbed in large amount, the theory that the color was produced by fungous growth seems the best. Scrapings from the discolored areas should be stained and examined directly and other specimens should be examined in the moist condition, preferably in potassium hydroxide solution, from 10 to 40 per cent strength depending on the thickness of the specimen if shreds of skin are included. Cultures should be made on suitable mediums for growth of bacteria or higher fungi.

4 Stains of the skin and hair by the dust of copper and certain salts of chromium are common among workers in these metals as mentioned by Schwarz and Tulipan (*Occupational Diseases of the Skin*, Philadelphia Lea & Febiger, 1939 p 728). White (R. Prosser *The Dermatogoses*, ed 4 London, H K Lewis & Co., 1934, p 67) also mentions the use of copper in some hair dyes, in paints, especially those intended for use on metals, and in the fibers of color in cotton goods.

Less common are cases of green sweat. Clifton (*Cases of Copper Poisoning Occurring Among the Outpatients of St. Thomas's Hospital*, *M Times & Gaz*, June 20 1868, p 658) noted in addition to green sweat staining the clothing especially after a hot bath, that these patients showed a green line on the gums next to the teeth and extending a short distance on the teeth. His patients, besides copper smelters, included a sailor who had been given lemon juice kept in a copper trunk and a girl who used Scheele's green, copper arsenite in making artificial flowers.

No record of any case of green discoloration between the toes has been found.

REMOTE TRAUMA AND DETACHMENT OF RETINA

To the Editor—I have a case of retinal detachment which is of the flat detachment type with disinsertion at the ora serrata. There is a question as to whether it can be due to an injury received. The injury consisted in the patient's head having come in contact with a solid brick wall or with a shelf which was placed firmly against the wall. There were mild concussion symptoms following the injury for several weeks. As far as has been ascertained there was no preexisting disease in the eye. The refractive error in the eye before the accident was minus 3.25 with plus 3.00 cylinder axis 65 with no appreciable change following the accident. I should like to have an opinion as to whether this case might be considered as of traumatic origin. The insurance company in this case has offered about one half of the amount that would normally be due on the policy as a compromise on what it terms as pay for the damage allegedly suffered from the concussion.

Mollory P. Weems, Captain M C A U S

ANSWER—This is one of the hardest questions that can be put to an ophthalmologist and ranks with a similar question as to the possible traumatic etiology of an interstitial keratitis in the presence of a positive Wassermann reaction.

Remote trauma, as in the instance cited, undoubtedly can and does play a role in the production of detachment of the retina, probably acting as the exciting mechanism in a diseased eye. The following quotation from Duke-Elder expresses the consensus on this subject:

"To a very large extent, these indirect injuries, which are usually small, act not as a primary cause of detachment but merely as the precipitating agent in an eye already prone to this accident. As we shall see later, the sudden strain determines the formation of a tear in the retina after other factors, such as

degenerative or inflammatory processes, have produced a region of weakness. In this sense, by acting as a trigger in starting a chain of events which have already been predetermined by other and more fundamental factors, minor and indirect traumas figure very constantly in the etiology of the condition.

"One point noteworthy in connection with contusions as an etiologic factor is the possibility of a considerable interval elapsing between the receipt of an injury and the recognition of symptoms. The occurrence of a delayed detachment may be due to several reasons, but probably the most common is that the retina is torn at the time of the accident but does not become detached or so extensively detached as to attract notice until some time has elapsed."

It must be noted that this deals only with indirect traumas. Direct trauma to the eye itself with subsequent detachment is another question.

PARAFFIN SULFANILAMIDE TREATMENT OF BURNS

To the Editor—Under the auspices of the Office of Civilian Defense a course in the treatment of war injuries has recently been given in the Los Angeles area. The local treatment of burns advised in this course was powdered sulfanilamide in paraffin. The prescription follows:

Paraffin wax	670 Gm
Petrolatum	250 Gm
Liquid petrolatum (heavy)	150 cc
Cod liver oil	50 cc
Sulfanilamide powder	50 Gm
Menthol	1 Gm
Camphor	1 Gm
Oil of eucalyptol	1 cc

It was advised that this material be heated in a water bath and sprayed on burned areas without any preliminary cleansing or debridement. It was further stated that this form of therapy had been widely used in industrial plants and was the accepted treatment of burns in the Naval Hospital, Mare Island. It was assumed that this form of treatment had the acceptance of the Office of Civilian Defense. If this treatment is efficacious there is no question of its adoption but I have been unable to find reference to its use or any attempt to compare it with other more usual local treatments of burns such as tannic acid either alone or in conjunction with silver nitrate, gentian violet or the triple dye application. Further, it was my belief that at least reasonable cleaning of burned areas was as much a factor in the prevention of subsequent infection as was the local application of medicaments. An obvious theoretical objection to the paraffin wax and sulfanilamide treatment is that most of the sulfanilamide will remain suspended in an inert medium (paraffin), where it will be unable to exert any bacteriostatic or bactericidal effect. Furthermore, it is my belief that paraffin and various oils have been used extensively in the past in the local treatment of burns and that most of these treatments had been discarded because of the superior results obtained from tanning agents or in some instances from wet dressings alone. I would appreciate any references to articles on this subject (paraffin and sulfanilamide spray) and also would like to know how extensively it has been used in industrial plants and with what results.

Kenneth B. Olson, M.D., Olive View, Calif

ANSWER—The form of burn therapy cited in the query is a modification of the ambrine and paraffin methods used since the time of the last war. Ambrine is a patented paraffin preparation introduced by Barthle de Sandfort in 1914. As the formula was kept secret several other paraffin preparations have been used since. Sherman (*W O The Paraffin-Wax or Closed Method of Treatment of Burns*, *Surg Gynec & Obst* 26 450 [April] 1918) remains to the present day an earnest supporter of the paraffin method of burn treatment, stating that he and his staff have treated over 100,000 cases in this manner at the Carnegie Steel Company, Pittsburgh. Few others, however, have continued this type of therapy since the close of the first world war despite the vogue that it enjoyed at that time.

An appraisal of any method of burn treatment is difficult because of many variables. These include the nature, extent, depth and duration (time after the burn when treatment is applied) of the particular burns involved. It would seem that the fourth variable (duration of the burn) would be the one most appropriate to a consideration of the cases treated at Mare Island. Reports in the popular press indicate that many of these burns were old, having already passed the initial period with its shock and other attendant dangers. These cases would therefore have reached the stage where tanning agents and certain other definitive treatments would not be applicable any way. To appraise a type of treatment accurately, a series of cases of fresh burns should be treated with the method and the series controlled with regard to all the variables listed.

It would seem likely that there would be only minimal absorption from or local action of sulfanilamide suspended in paraffin. Sulfonamides or cod liver oil have little proved specific advantage over a simple bland petrolatum dressing with careful preliminary cleansing and pressure as advocated by Koch (Siler, V. E., and Reid, M. R. *Clinical and Experimental Studies with*

the Koch Method of the Treatment of Heat Burns, *Ann Surg* 115 1106 [June] 1942) Furthermore, while the Mare Island treatment may not take so long to apply the daily reapplications will certainly take as much time in the end as sealed methods (tanning or Koch petrolatum pressure) which require no change for at least ten days to two weeks. It is also difficult to see how any remedy for fresh burns can be useful which does not depend on a thorough preliminary cleansing of the wound as is especially advised by Koch. Since this is less essential—and in fact even useless—in old burns perhaps this may explain the apparent success of some of the Mare Island cases.

In conclusion, it can be stated that this method presents only slight apparent practical advantages over the standard paraffin treatment. The most recent recommendations of the National Research Council (*War Med* 1 334 [March] 1942) make no mention of either the original or the revised form of paraffin application. Finally, before being condemned or accepted, the treatment should be tried on a controlled series of burns and contrasted with other methods in popular use.

CHILOMASTIX IN INTESTINES

To the Editor—A man aged 57 with symptoms of chronic appendicitis was found to have an eosinophil count of 7 per cent. This with the history of having worked in the Philippine Islands for four years led to a thorough study of the intestinal tract. After a saline purge *Chilomastix mesnili* was found in the third and fourth stools. Even though amebae could not be found the patient was treated with emetine hydrochloride and carbarsone for ten days and placed on a high protein diet. After a rest period his appendix was removed. Six weeks later stool examination was repeated and *Chilomastix mesnili* was still present in the third and fourth stools. All available literature has revealed little or nothing about the pathogenicity and method of eradication of these organisms. Will you please give an outline of methods used for the eradication of intestinal flagellata?

James C Coffey MD Salisbury N C

ANSWER—*Chilomastix* inhabits the colon of man. It does not invade the tissues. Although it is often found in the presence of diarrhea, it is more often found in the absence of symptoms. It is possibly the cause of diarrhea when present in huge numbers. It is doubtful that it had any pathologic significance in relation to the chronic appendicitis in the case cited. Carbarsone has apparently been responsible for the removal of this infection in a few cases. It can be given by mouth in doses of 0.25 Gm four times a day for seven to ten days. This is twice the usually recommended dose for amebiasis, but the drug can be used in this dosage for either infection with practically no fear of toxic symptoms. The elimination of carbohydrates from the diet also assists in reducing and possibly eliminating *Chilomastix*. The same regimen of treatment may eliminate *Trichomonas hominis*, which also inhabits the colon. *Giardia*, which inhabits the duodenum and jejunum, is not affected by the treatment outlined but can often be eliminated by atabrine dihydrochloride 0.1 Gm two or three times a day by mouth after meals for three to five days.

AIR STERILIZATION WITH GLYCOL VAPORS

To the Editor—A newspaper publisher has just asked me about a spray containing a small portion of one of the glycols which so he heard might be incorporated into the humidifying system of the building and by sterilizing the air perhaps might lessen the incidence of respiratory infections among employees. I realize that no disinfectant can prevent droplet infection such as would come from a cough or sneeze but if decreasing the number of bacteria in office air is at all practicable (without rendering the air irritating or odorous) it should be valuable. Can you give me any information or refer me to the proper authority? Ultraviolet generators would not do.

D G Ornston MD Philadelphia

ANSWER—The studies on air sterilization with glycol vapors and in particular propylene glycol which are being carried on by O H Robertson and his associates at the University of Chicago have not yet reached the point where practical application can be advocated. These workers feel that definite information concerning any possible deleterious effect on the lungs resulting from prolonged inhalation of propylene glycol vapor must be obtained in appropriate animals before exposing human beings to such atmospheres. Observations on long term animal toxicity tests of this nature in both rats and monkeys have been under way for many months. Furthermore, certain problems concerning the best means and most suitable apparatus for distributing glycol vapors are not yet solved. While introduction of propylene glycol vapor into an air conditioning system of a building would seem to promise a simple means of distributing this vapor, little information is yet available concerning the possibility of obtaining adequate concentrations of the vapor in all parts of an enclosed air space. Such questions as to how much of it would be absorbed on various kinds of surfaces, the

effect of dust, and the like need to be elucidated. Preliminary reports on this work by the authors mentioned may be found in the *Journal of Experimental Medicine* (75 593 [June] 1942) and *Science* (94 612 [Dec. 26] 1941).

VIABILITY OF KIDNEY AFTER URETERAL OBSTRUCTION

To the Editor—Will you kindly give me an opinion as to the length of time a kidney may remain viable and retain its normal function when its ureter has been completely blocked by an impacted calculus producing complete anuria on the affected side if the calculus is removed surgically? I do not have reference to complete blockage resulting in acute fulminating symptoms since it is fully understood that such a condition demands immediate surgical intervention but rather to complete blockage with resultant anuria without constitutional symptoms. This complete blockage was proved by numerous cystoscopies and no excretion of urine was found to exist. Methylene blue was injected and the catheter left in the ureter for over an hour on several occasions so there is no possibility of error having been made. The injection of the dye was intravenous.

John E Hall MD Miami Fla

ANSWER—The duration of viability of the human kidney following complete ureteral obstruction is not known with certainty, but from clinical experience and experimental evidence available such kidneys are capable of a return of function even after several weeks of complete ureteral occlusion. In some cases with ureteral obstruction a diagnosis of functionless kidney is made because of failure of renal visualization in the excretory urogram and the absence of dye in chromocystoscopy from the affected kidney. Such cases have been observed in which visualization was absent over a period of several months and when renal drainage was reestablished, renal function returned to normal within a short time. However, failure of urographic visualization is not necessarily an indication of complete anuria, since in many cases of this type cystoscopic inspection of the ureteral orifices may reveal spurts of a pale, water-like urine which has a low specific gravity and may contain no dye following chromocystoscopy. Such secretion would indicate a limited activity of the kidney. Moreover, in most of these cases of partial occlusion intermittent symptoms of dull pain are present, which would also indicate persisting renal function. After the obstruction has been removed the kidney often returns to normal, even after months of partial occlusion. Partial renal occlusion, however, is quite different from the case cited in this query, in which there is complete absence of any renal secretion, apparently over a period of several weeks, and without any constitutional symptoms. This type of case is not frequently reported but undoubtedly is not of rare occurrence.

The experimental evidence available suggests that the duration of complete ureteral obstruction required for total destruction of the kidney depends to some extent on the size and consistency of the animal's kidney. Approximately forty days is required for complete destruction of the kidney in the rat and eighty-four days in the rabbit. Working with dogs Caulk and Fischer found that after complete ligation of the ureter the kidney was severely damaged at the end of two weeks. Joelson Beck and Moritz however found that, if the dog's ureter was completely ligated for periods of from twelve to nineteen days renal function could be restored in from forty to seventy days by reimplantation of the ureter or by nephrostomy. It would be logical to assume that if a ureter was completely ligated the renal function would be so completely destroyed at the end of a month that ureteral reimplantation or renal drainage would permit little recuperative power. It is possible, however, that under favorable circumstances the human kidney may have somewhat greater recuperative power.

Another factor which exercises an influence on the time interval required for destruction of the kidney is the level of interpelvic pressure present after ureteral occlusion. It has been shown experimentally that immediately following complete ureteral occlusion the intrapelvic pressure rises to 75 or 100 mm of mercury pressure, which, after a period of several hours falls to a much lower level. This is due both to diminished renal excretion and to reabsorption of the urine. Since the high initial pelvic pressure, or the force serving to dilate the kidney, is present for only a short while, it is perhaps easily understood why complete ureteral obstruction over a period of several weeks might be required for destruction of the kidney. Furthermore, despite complete ureteral obstruction, some degree of renal excretion and reabsorption is continuously taking place and it therefore hardly seems correct to assume that the renal function has been held in complete abeyance all this while.

Clinical and experimental evidence would lead one to believe that in case of carefully proved complete absence of urinary secretion resulting from obstruction continued over a period of a month or longer, and in the absence of recent pain or constitutional symptoms the affected kidney has been so severely damaged that removal of the stone and reestablishment of renal

dramage will not restore renal function. It would seem probable that in the case cited the affected kidney has suffered irreparable damage and is largely, if not completely, destroyed. In fact, in the absence of urgent clinical data, surgical intervention is hardly indicated.

ITCHING FROM BURNS IN BOY AGED FOUR

To the Editor—A 4 year old boy is now convalescing from a rather extensive burn of his chest and back. Although he is up and around and his wounds are completely healed he is subject to periodic recurrences of intractable itching of the scorched areas which initiate a sudden wild frenzy of scratching, thumping his chest and back accompanied by crying and screaming. Could you advise me of any local application which could be used for a long period and yield a satisfactory analgesic effect locally without any systemic sedation or toxic effects?

Leo Dobrin, M.D., New York

ANSWER—It is quite possible that what this patient actually needs is a skin grafting procedure. However further details would be of help in answering this question. These involve especially the type of original burn treatment, how large a granulating surface resulted in it, and the time which has elapsed since the original burn and since the healing of the granulating wound, if any. If a large granulating wound was produced by the burn (which would therefore have been a third degree injury) the resultant scar tissue is entirely different from that which follows a first or second degree burn. This scar tissue is prone to break down to cause contractures and—what is especially apropos to the patient under discussion—to not keep up in rate of growth with the surrounding more normal tissues of a boy of 4 years. It has been shown (Brown, J. B. Covering of Raw Surfaces. *Internat Abstr Surg* 67: 105, 1938, in *Surg, Gynec & Obst*, Aug 1938), that the scar base following a third degree burn is composed of flat epithelium without hair, glands or papillae. Because of lack of supporting rootlike action of the normal papillae, such skin is readily stripped up in sheets as the result of relatively mild trauma.

The most successful method of treating such scar tissue is by means of skin grafting. Since it is extremely difficult to obtain satisfactory thick split grafts of sufficient size taken with a razor or Blair-Brown knife from a 4 year old child, dermatome grafts usually give the most satisfactory result. Before applying the grafts, the entire scar should be excised and the graft applied to the normal tissue beneath. This advice is given on the premise that a third degree burn existed. The technique of applying dermatome grafts is described by Pridgett (*Skin Grafting*, Springfield, Ill., Charles C. Thomas, 1942).

In case the burn was not third degree, skin grafting would not be indicated. The use of daily applications of cocoa butter or of anhydrous wool fat should be tried. This may be continued for some time while medicated remedies (e.g. calamine lotion with phenol) should be used for only a few weeks at a time and should not be placed under occlusive dressing.

Calamine lotion with phenol alternated with plain olive oil or with calamine liniment (N.F.) may be useful as an antipruritic.

INFANT FEEDING DURING EARLY HOURS OF LIFE

To the Editor—Will you give me the current opinion regarding the following. When using artificial feeding for the newborn which method prevails (a) sterile water and Karo for the first twenty-four to forty-eight hours (b) small feedings of formula and (c) use of laxatives?

R. F. DeWitt, M.D., Plymouth, N. H.

ANSWER—At one large hospital newborn infants do not receive any food other than sterile water and the breast during the first seventy-two hours. No laxatives are prescribed. The objective in omitting feedings is to create a desire for food on the part of the infant which will lead him to stimulate the mother's breast. Six hours after birth the infant is placed to the breast for the first time and thereafter at four hour intervals, five times daily.

DANGERS OF SULFUR DIOXIDE TO REFRIGERATOR WORKER

To the Editor—One of my patients is a refrigerator service man, and in the course of his work he frequently brings his hands into contact with sulfur dioxide. This chemical stains and irritates his hands and causes him a great deal of discomfort. Will you be kind enough to advise me what chemical he may use with safety to neutralize the irritant after exposure? He has tried wearing protective gloves but finds that they interfere with the manipulation of his fingers.

J. Joseph Klor, M.D., Springfield, Mass.

ANSWER—The chief danger to refrigerator workers from sulfur dioxide is from freezing. A needle sized jet from a leak will freeze an eyeball immediately. Chilling of other portions of the body from contact with liquid sulfur dioxide is rapid but less significant than eye freezing. Much sulfur dioxide as used in refrigerators is dissolved in oil. This practice diminishes the prospect of injury to workers. Ordinarily sulfur dioxide does not stain in the ordinary sense but instead bleaches, as is well known from its wide use in bleaching dried fruits. If retinal staining occurs, this is more likely to be associated with grime from contact with oil. It is well established that sulfur dioxide is a hygroscopic agent leading to skin desiccation from the extraction of water, which eventuates in the formation of an acid. No chemical application can be expected to overcome chilling from sulfur dioxide, but irritation may be prevented by the application before and during the course of work, of a small amount of any tenacious substance such as hydrous wool fat preferably with some mild alkali such as sodium bicarbonate. The quantity required, two or three times daily as rubbed on the skin of the hands, is so slight as not to interfere with work and not to be unsightly. It is not sufficient to use such protection only after exposure, as implied in the query. Benefit will arise chiefly by preventing contact between the skin and the sulfur dioxide.

UNUSUAL REACTION TO MECHOLYL CHLORIDE

To the Editor—Recent literature dealing with the toxicity of the glycols prompts the following case history. A woman aged 45 suffered urinary retention for approximately six weeks following cystoscopy performed for diagnosis and treatment of a left-sided pyelitis of mild degree. When all usual attempts to relieve the retention failed and the patient was leading a catheter life with no signs or symptoms of genitourinary disease a neurologic consultation was obtained. The ultimatum was that psychogenic factors alone caused the condition. It was suggested that mecholyl chloride be administered hypodermically in doses of 25 mg each. The patient had a course of twelve injections. The drug was packaged as a dry powder in an individual ampule to be dissolved in distilled water. Before each injection the blood pressure cuff was attached and the patient made comfortable in bed. A hypodermic containing atropine sulfate 1/100 grain (0.00065 Gm.) was kept in readiness. The initial arterial tension was 145 systolic, 85 diastolic and within two minutes of administration of the mecholyl, in each of the twelve doses, the systolic pressure began to fall. Concomitantly the patient complained of a flush of a musty unpleasant odor and of profound perspiration. The pressure reached its lowest point in approximately eight minutes averaging 95 systolic and 70 diastolic. After this it slowly climbed until in fifteen to twenty minutes from the start it attained its original level. Aside from the unrelenting sweat there was no aftereffect in any instance. After the second injection the patient voided urine spontaneously before retiring making catheterization necessary only in the morning. This situation obtained for the rest of the course. The third purchase of mecholyl consisted of 25 mg in each ampule but it was already dissolved in propylene glycol. The usual precautions were taken and the substance was injected hypodermically. In about one minute the patient complained that she felt warmer than usual. In another minute I noted that the systolic pressure began to rise and the pulse which previously had remained fairly constant throughout the effect also increased. When sweating failed to appear I realized that a different reaction was in progress. When the systolic pressure reached 210 and the pulse 130 (in the fifth or sixth minute) the patient had a generalized tonic convulsion. She had not made a sound since complaining of the flush but simply lapsed into a coma. The pupils could not be examined because the eyes were rolled upward and rigidly fixed in that position. The fingers of the clenched fists could not be pried open, the forearms could not be extended nor could the lower limbs be moved in any manner. Respiration was about 18 to 20 per minute and shallow. I administered 1/10 grain (0.0013 Gm.) of atropine followed in two minutes by a similar dose. The peak of blood pressure (250/140) and pulse (something over 180) came just prior to the second injection of atropine and about twenty minutes after the mecholyl. Gradually the signs abated. In about forty-five minutes the extremities could be moved with some difficulty and in another fifteen minutes the patient stirred voluntarily and made a grimace of pain. In a half hour she could answer questions but indicated that every effort gave bodily pain in particular a severe frontal headache. It took two days for the last of the symptoms to subside and the arterial tension and pulse to reach their former level. Total retention again set in and on the day of writing (five days after injection) has not been relieved.

SULFONAMIDE COMPOUNDS IN THE PREVENTION AND TREATMENT OF WOUND INFECTION

A CONSIDERATION OF THE PRINCIPLES
WHICH GOVERN THEIR USE

PERRIN H LONG, M.D.
BALTIMORE

The introduction of the use of sulfonamide compounds as prophylactic and curative agents in the field of surgery has not been an unmitigated blessing for surgeons because of a growing tendency to neglect fundamental principles of good surgical judgment and technic and to rely instead on the wholesale use of the "wonder drugs." This undesirable condition has been brought about by a false impression that the sulfonamide compounds are "cure-alls" and represents a current trend toward an ignorant complacency in respect to the elective and selective uses of these agents.

There can be no questioning the fact that these drugs have frequently saved the patient of the careless surgeon from disaster, but when the sulfonamides fail because of neglect of the use of sound judgment and surgical technic, coupled with a lack of knowledge of the fundamental principles of sulfonamide therapy, then too often these drugs are berated as being worthless, when the truth of the matter is that the primary principles of the surgical aspects of the patient's care have been cast aside. One must remember (and too often in the present this fact is being forgotten) that the use of sulfonamide compounds is an adjunct to surgical therapy and cannot replace it. However, these drugs can be valuable aids when properly employed and have permitted the development of certain advances in surgical practices which were considered unattainable before the advent of sulfanilamide and its derivatives.

With the establishment of the proposition that sulfonamide therapy is a valuable adjunct to adequate surgical treatment, the problem of their use in the prophylaxis and therapy of contaminated and infected wounds becomes simplified. In civilian practice it has been established that many contaminated wounds can be closed directly after an adequate toilet of the wound has been completed. However, in war wounds (except for very minor lacerations) experience has shown that primary closure is dangerous, and with few exceptions (perforations of the chest or abdomen) such wounds should be left open. It is of interest to recall at this point that the adequate use of locally implanted sulf-

anilamide in the wounds of our casualties in Hawaii prevented wound infection, thereby permitting the debridement of some wounds many hours after they had been incurred. Then after a few days the wounds were so clean that some were secondarily sutured and healing by first intention occurred.¹ Infected wounds should always be left open.

In any consideration of the use of sulfonamide compounds in the prophylaxis or treatment of wound infection, several factors must be considered and among these are the type of surgical procedure employed, the condition of the wound at the completion of surgical treatment, the determination of whether oral and/or local sulfonamide therapy will be used, the proper selection of the drug for peroral or local use, the dosage to be used, the duration of treatment and finally the utilization of the correct postoperative care in order that the greatest benefits may be derived from the employment of the sulfonamide compounds.

It has been established that the sulfonamides can be used in the treatment of wounds regardless of the type of surgical procedure that has been employed. As far as is known at the present time, the administration of these drugs is compatible with the use of standard intravenous, inhalant or local anesthetics, and they will not influence adversely either the course or the treatment of traumatic or infectious shock.

The condition of the wound at the time sulfonamide therapy is used is of importance. Obviously a poorly debrided, carelessly drained fresh wound is an unsuitable site for the implantation of the sulfonamides and under such conditions the drugs may eventually fail to exert their prophylactic effect. The method of wound closure is important. Implanted sulfonamide compounds may cause an exudation of tissue fluids into the wound, and sloughing of the wound edge has been noted as a result of the tension created by these fluids when wounds have been closed too tightly. This possibility should be kept in mind when one is dealing with lacerations in which especial consideration must be given to the final cosmetic effect. It has been shown² that necrotic material or pus contains sulfonamide inhibitors, hence every effort should be made to eliminate and neutralize these substances before sulfonamide therapy is started.

The experience of the last few years has shown that oral, topical or oral plus topical medication with the sulfonamides will prevent wound infection. However, the best evidence available at the present time shows that the administration of these drugs by the peroral

and local routes is to be desired in the prophylaxis of infection in moderate or serious wounds of the soft tissue, compound fractures, compound skull or facio-maxillary injuries and penetrating wounds of the abdomen or chest. Infection can generally be prevented in minor lacerations involving the skin and subcutaneous tissues or superficial muscle layers, without extensive destruction of tissue, by the topical application of a sulfonamide compound.

In the selection of the drug of choice for the peroral prophylaxis or therapy of wound infection, the effectiveness of the drug and its toxicity are primary considerations. It has been shown that sulfadiazine is clinically effective against systemic infections produced by staphylococci, hemolytic streptococci, colon bacilli and members of the aerogenes group. In clostridial infections this drug has been proved active against experimental infections produced by *Clostridium perfringens* or *Clostridium septicum*. It offers a wide range of protection against the common primary contaminating and infecting organisms in wounds.

A recent survey which we have made of the occurrence of the important toxic reactions (fever, rash, acute hemolytic anemia, leukopenia, acute agranulocytosis, renal complications and hepatitis) of sulfanilamide, sulfapyridine, sulfathiazole and sulfadiazine shows that a total of 11.9 per cent of such reactions occur in the course of sulfanilamide therapy, 15.9 per cent when sulfapyridine is employed, 18.6 per cent if sulfathiazole is used and but 6.5 per cent when therapy is conducted with sulfadiazine.

In addition, sulfadiazine produces comparatively little nausea and vomiting and rarely any degree of cyanosis, mental disturbances and incoordination are uncommon, endurance is not seriously affected, and acidosis or a lowering of the plasma carbon dioxide content does not occur. The lack of these side effects is of importance in any consideration of the ambulatory wounded and in the transportation by air of injured patients. Against these favorable factors is the known ability of the drug to produce renal damage. Observations made by my associates and me show that one can expect that in about 17 per cent of patients receiving average doses of this drug either microscopic or gross hematuria will develop while in 0.4 per cent oliguria, azotemia or anuria develops. It is known that a decreased fluid intake with a resulting decrease in the output of urine predisposes a patient to this type of renal complication. Hence, when water is scarce, as in desert warfare, or when temperatures are high and loss of body water is great, the threat of kidney damage might be considered a deterrent to the use of sulfadiazine. However, the occurrence of this complication appears to be greater when sulfapyridine or sulfathiazole is administered, and one must remember that sulfanilamide produces hemolytic anemia in about 2 per cent of patients to whom it is given. After an evaluation of the various factors involved, it seems reasonable to conclude that, while sulfadiazine can produce serious toxic reactions, it is the least toxic of the four commonly used sulfonamide drugs and is the drug of choice for the peroral prophylaxis of contaminated wounds and for the peroral therapy of infected wounds. If sulfadiazine is not available, sulfanilamide or sulfathiazole should be used in the order named in the peroral prophylaxis or therapy of contaminated or infected wounds.

Confusion exists in respect to the topical use of sulfonamide compounds. For example it is commonly assumed that because sulfathiazole is more effective

than sulfanilamide in the systemic therapy of staphylococcal infections, its topical use is always indicated when the possibility or the presence of staphylococcal infection exists. This assumption is not necessarily correct because various factors such as the physical characteristics and solubility of the drug, its antibacterial effect in the upper ranges of its solubility, its rate of diffusion and absorption from the local lesion, the effect produced by its local implantation on tissue repair and wound healing and the systemic toxic effects which the drug may produce enter into any consideration of the selection of the drug of choice for topical use in the prevention or treatment of contaminated or infected wounds.

It has often been observed that when too finely powdered sulfonamide compounds are placed in wounds they tend to "craze." Sulfonamide compounds for topical use, consisting of large crystals or coarsely ground forms of these drugs, dissolve slowly in wounds and tend to initiate foreign body reactions. While the ideal crystal size of these compounds is not definitely known it has been shown that satisfactory results can be obtained when crystalline sulfanilamide screened to 40 to 80 mesh is used.

The solubility and diffusibility of the compounds under consideration for local use is of importance. Sulfanilamide is soluble in tissue fluids to the extent of from 1,200 to 1,500 mg per hundred cubic centimeters and has been shown by Hawking³ to diffuse rapidly through living tissue and fairly well through dead tissue. This observer has demonstrated that sulfathiazole, sulfapyridine and sulfadiazine are much less soluble (18.4, 61 and 124 mg per hundred cubic centimeters in human serum at 36 C respectively) than is sulfanilamide and that sulfapyridine and sulfathiazole diffuse more slowly through living tissues. In our experience sulfadiazine behaves like sulfapyridine as far as diffusion is concerned. This variation in the solubility of the drugs is important in estimating the possible antibacterial effects of these compounds when they are employed as topical agents, and it has been shown in vitro that in the upper range of its solubility sulfanilamide seems to be as effective an antibacterial agent as are the other sulfonamide compounds at their limits of solubility. This observation is important in the consideration of the sulfonamide drug of choice for local use in the prophylaxis and treatment of wound infections.

As has been pointed out, sulfanilamide diffuses more rapidly from the site of its implantation than do the other sulfonamides, and following the topical use of crystalline sulfanilamide in closed wounds peak concentrations of the drug in the blood can be expected in from six to twelve hours, with absorption and excretion of the drug being practically completed within forty-eight hours unless massive doses of sulfanilamide have been used locally. The peak concentrations of this drug in the blood are considerably higher than those noted following the local use of sulfathiazole, sulfapyridine or sulfadiazine in wounds that are closed.

The latter compounds, because of their lower solubilities and rates of diffusion, are absorbed and excreted more slowly than is sulfanilamide, and in the instance of sulfadiazine we have noted that following the implantation of 5 Gm of the drug in an extra-peritoneal wound of the abdominal wall absorption of the drug continued for more than two weeks.

3 Hawking, Frank. *Lancet* 1: 786 (June 21) 1941.

There is not a great deal of information available regarding the absorption of sulfonamide compounds from open wounds. Veal and Klepser⁴ have reported that the instillation of 7.5 Gm of sulfanilamide into an "open clean wound (pilonidal sinus excision)" produced a peak concentration of the drug of 2 mg per hundred cubic centimeters within five hours and at forty-two hours very small amounts (less than 0.5 mg per hundred cubic centimeters) of the drug were found in the blood. Another of their patients suffering from an open wound of the abdominal wall was given the daily implantations of 5 Gm of sulfanilamide, followed by a gradual rise of the concentration of the drug in the blood to 12 mg per hundred cubic centimeters on the sixth day. At the end of thirty-six hours the concentration of sulfanilamide in the blood was 3 mg per hundred cubic centimeters. These observations, coupled with those of our own, lead us to believe that excessive concentrations of sulfanilamide are not to be expected following its use in open wounds. In burns, the opposite seems to be true. Hooker and Lam⁵ have shown that when crystalline sulfanilamide is applied to second or third degree burns absorption may be rapid and excessive concentrations of the drug may occur in the blood. Our own observations show that sulfathiazole and sulfadiazine are less readily absorbed from open wounds than is sulfanilamide.

The differences in the solubility of the various sulfonamide drugs appear to bear some relation to their effects on wound healing. It has been shown⁶ that in concentrations up to approximately 500 mg per hundred cubic centimeters, sulfanilamide has little if any effect on the multiplication of fibroblasts in tissue cultures and that, while this drug does inhibit certain cellular functions in higher concentrations, the recovery of the cells from its unfavorable action is rapid and complete when they are removed from excessive concentrations of the drug. Sulfathiazole⁷ has been shown to be the least favorable for growth at any assigned concentration, and as far as sulfapyridine and sulfadiazine are concerned their limited solubility does not permit the accurate testing of their effects on cells in tissue cultures.

It seems well established that the degree of solubility of the various sulfonamide drugs has a definite bearing on their ability to produce foreign body reactions when they are implanted locally. Sulfanilamide, because of its high solubility, is least likely to produce this reaction within wounds, with sulfathiazole, sulfapyridine and sulfadiazine in the order named having increasing possibilities of producing such a reaction.

As far as direct toxic effects on various types of tissue are concerned, there is disagreement concerning the action of the sulfonamide drugs. Russell and Falconer⁸ reported that the application of finely powdered sulfanilamide or sulfapyridine to the leptomeninges or the cortex of the rabbit did not produce appreciable damage within four days. Hurteau⁹ has confirmed and extended these observations and has further reported that while sulfadiazine is slowly absorbed from brain tissue no glial reaction occurs after the implantation and but a slight foreign body

reaction in the meninges. Taffel¹⁰ on the other hand, has noted that all of the commonly used sulfonamides produced a mild inflammatory reaction when applied to the cortex in monkeys. Sulfathiazole seemed to produce the most intense inflammatory response while sulfadiazine caused the most severe foreign body reaction. These observations are of especial interest in view of the recent report of Watt and Alexander¹¹. These observers noted that the application of crystalline sulfathiazole to the frontal cortex in both human beings and dogs frequently produced epileptiform convulsions. This phenomenon did not occur when sulfanilamide sulfapyridine or sulfadiazine was used.

Taffel and Harvey¹² reported that the local application of crystalline sulfanilamide did not interfere with the healing of experimental wounds in the stomachs of rats. Harbison and Key¹³ have confirmed this observation and have further reported that the implantation of crystalline sulfanilamide did not disturb the healing of wounds produced in the abdominal walls of rats nor did this drug produce adhesions when introduced into the peritoneal cavity of rats.

Glynn¹⁴ states that crystalline sulfanilamide has "a slight but definite toxic reaction on striped muscle" but that this drug does not inhibit fibroblastic proliferation in wounds produced in rabbits. Taylor¹⁵ however, has reported that all these drugs produce inflammatory tissue reactions when implanted into wounds in dogs and that in the case of the less soluble drugs the reactions may be so severe that actual tissue destruction and sterile abscess formation occurs. Finally, Bick¹⁶ has recently observed that "the local application of sulfonamide drugs to wounds of the soft tissues or cleancut operative incisions in which primary suture is indicated retards healing by at least 50 per cent of the time factor and promotes extensive cutaneous scarring."

As has been previously described the local application of the sulfonamide drugs to wounds may cause an exudation of tissue fluids, which in the instance of a tightly sutured wound may cause tension and delay wound healing. Our observations lead us to believe that sulfathiazole and sulfadiazine are more likely to produce such an exudation of fluid than is sulfanilamide.

Out of the welter of conflicting experimental and clinical reports which I have just reviewed one fact seems to emerge, namely that, while the local implantation of sulfanilamide may interfere to a certain degree with wound healing it appears to be the least harmful of the commonly used sulfonamides to regenerating tissues.

Thus when all the factors have been considered it seems reasonable to choose sulfanilamide as the drug of choice for the prophylaxis and treatment of contaminated and infected wounds.

In considering the peroral prophylactic dose of sulfadiazine needed for the prevention of wound infections, civilian injuries must be differentiated in general from war casualties. In the first instance, definitive surgical treatment will probably be given promptly and in most cases the administration of sulfadiazine by mouth can

be deferred until just prior to or after definitive surgical treatment. In the case of persons wounded as the result of enemy action, definitive surgical treatment may be delayed for many hours, therefore, the prophylactic dose of sulfadiazine should be given as soon as possible after the wound has been incurred.

For adult civilian injuries, the initial peroral dose of sulfadiazine should be 2 to 4 Gm given either immediately before or after definitive surgical treatment, this to be followed by 1 Gm of the drug every six hours for two days, following which doses of 0.5 Gm every six hours should be administered for eight days.

For adults wounded as the result of enemy action the initial peroral dose of sulfadiazine should be 4 Gm. This should be given as soon as possible. After this initial dose no more of the drug should be given by mouth until after definitive surgical treatment has been completed. Then sulfadiazine 1 Gm every six hours should be administered day and night for from seven to ten days. If infection occurs despite the attempt at prophylaxis, the administration of the drug should be continued until the infection is under control. It is important to maintain a daily output of urine of at least 1,000 cc during the period of treatment in order to lessen the possibility of the occurrence of renal complications. If sulfadiazine is not available, sulfanilamide or sulfathiazole prescribed in the same dosage may be used. For injured children doses of these drugs should be adjusted according to the weight of the child in comparison with the adult dose.

There is a tendency at the present time to dump sulfonamide compounds haphazardly into wounds. This is a bad practice, and it should be emphasized that the implantation of sulfanilamide should be done carefully in order that all parts of the surface of the exposed wound will be in contact with the drug. A shaker-top container makes this easy, although many physicians prefer to use a powder atomizer for applying sulfanilamide locally.

In wounds that are closed by primary suturing, the amount of crystalline sulfanilamide implanted should approximate 0.05 Gm per square inch of wound surface. This represents a light "frosting" of the wound. In contaminated wounds in which closure is not indicated or in infected wounds 0.1 Gm of crystalline sulfanilamide per square inch (2.5 cm) of wound surface should be used. This represents a heavy "frosting" of the wound. On the basis of our present experience it would seem that not more than 10 Gm of sulfanilamide should be given locally to any given patient within a twenty-four hour period.

The combination of sulfadiazine by mouth and sulfanilamide locally will produce sulfonamide concentrations in the blood of from 6 to 16 mg per hundred cubic centimeters in the first twenty-four hours in patients whose wounds are closed. If however, the wounds are left open, concentrations of the sulfonamide in the blood of from 5 to 10 mg per hundred cubic centimeters will generally be noted in the first twenty-four hours of therapy.

It has been mentioned previously that peroral therapy with sulfadiazine may be discontinued in from seven to ten days if symptoms and signs of infection are lacking. However, experience has repeatedly shown that it is necessary to repeat the local application of sulfanilamide to wounds at each dressing period if both primary and secondary wound infection is to be prevented. Local therapy with sulfanilamide should be continued until healing is complete.

As has been pointed out before, the successful treatment of contaminated or infected wounds is influenced by the amount of necrotic tissue or purulent material in the wounds, because these substances act as sulfonamide inhibitors. Therefore, if a wound shows evidence of infection it should be gently irrigated with isotonic solution of sodium chloride at each dressing or, perhaps better, with a mild oxidizing agent such as a 1:3,300 solution of azochloramid. (Such solutions should be stored away from the light in brown glass bottles.) It has been shown that the latter compound is effective in neutralizing the effects of sulfonamide inhibitors and indeed there is some evidence¹⁷ that azochloramid acts synergistically with the sulfonamides. Recent experience has also shown the value of utilizing dressings moistened with a 1:3,300 solution of azochloramid in the prophylaxis of contaminated and the treatment of infected wounds. These dressings can be placed in the wound after crystalline sulfanilamide has been applied and sealed over with boric acid ointment or petrolatum gauze to prevent them from drying. It is important to keep the wound dressing moist in order to prevent the caking of implanted sulfonamides.

Other substances have been reported as being effective in removing the effects of the sulfonamide inhibitors found in pus and necrotic material. Veal and Klepser⁴ used allantoin in combination with sulfanilamide in an ointment base and reported that this mixture stimulated the growth of healthy granulation tissue. Holder and MacKay¹⁸ have reported that a carbamide-sulfanilamide mixture gave excellent results when used in the local prophylaxis and treatment of contaminated or infected wounds.

SUMMARY AND CONCLUSIONS

The use of sulfonamide compounds for the oral and topical prophylaxis or treatment of contaminated or infected wounds is a valuable adjunct to careful surgical treatment but cannot replace it. However, the rational use of the sulfonamides has permitted the development of certain advances that were considered unattainable before the advent of sulfanilamide and its derivatives.

The broad general principles which govern the chemotherapy of wounds are applicable regardless of the anatomic location of the wound. On the basis of present evidence, it would seem that a combination of systemic with local therapy offers the best chance for the prevention of wound infection and for its cure once an infection has become established. On the basis of current evidence, sulfadiazine by mouth seems to be the drug of choice for systemic therapy, and the dose of the drug should be adjusted so that concentrations of from 4 to 7 mg per hundred cubic centimeters are obtained in the blood. Higher concentrations of the drug are probably unnecessary. From all points of view, sulfanilamide seems at the present time to be the drug of choice for topical application. It is to be remembered that necrotic tissue and pus contain sulfonamide inhibitors and that every effort should be made to eliminate these inhibitors before sulfanilamide is applied locally. Care should always be taken to prevent the caking of sulfanilamide in the wound, and this can be accomplished by applying moist gauze dressings following the application of sulfanilamide to the wound. In the absence of clinical infection, there is little reason to continue oral therapy with sulfadiazine for more than five to seven days. However, to prevent secondary

infections from occurring after primary prophylaxis has been successful, it is necessary to apply sulfanilamide powder locally until wound healing is complete

615 North Wolfe Street

ABSTRACT OF DISCUSSION

DR JOHN E CANNADAY, Charleston, W Va My experience with sulfonamide compounds in wounds has been that both sulfanilamide and sulfathiazole may be used satisfactorily in both clean and infected wounds, that they lower the incidence of infection in both types of wound and that when used in moderation they do not cause appreciable delay in wound healing I spread these drugs evenly throughout the wound and, in the case of sulfathiazole, rub it into the tissues in order to avoid the formation of lumps such as others have described It has been well established that sulfanilamide, when used in wounds is completely absorbed in the course of about two days and that under similar conditions sulfathiazole requires five or six days for absorption Likewise it has been amply demonstrated that if sulfathiazole is placed in the wound in lumps or masses it probably will not be entirely absorbed and may act as a foreign body A recent check-up on 1,281 consecutive abdominal surgical cases of myself and my associates in the surgical service of the Charleston General Hospital, the general surgical technic being the same in all cases, shows that of 910 uninfected wounds closed with cotton thread used in accordance with the Halsted silk technic there were 7 infections, or 0.77 per cent Of 129 uninfected wounds closed with catgut there resulted 8 infections, or 6 per cent Of contaminated wounds, 175 sutured with cotton, there were 30 infections, or 17 per cent Of 31 contaminated wounds closed with catgut there were 8 infections, or 26 per cent All these wounds, both uninfected and contaminated, were irrigated thoroughly with saline solution and either sulfanilamide or both sulfanilamide and sulfathiazole were placed in them In this series there were 18 gastric resections for ulcer with no apparent infections but with 1 wound disruption which followed a persistent cough This disruption was closed soon after it took place and healed without infection In the entire series of uninfected wounds there were approximately 12 that had a brief serous leakage for a few days but healed without pus formation While we cannot expect everything from the use of sulfonamide compounds in wounds, we do believe that when used in conjunction with adequate hemostasis, wound irrigation or accurate suturing (especially with cotton thread) they definitely help to lower the incidence of infection in both uninfected and contaminated wounds, and that if infection does follow their use the severity is at least lessened

DR PHILIP LEWIN, Chicago I should like to ask Dr Long to discuss combinations of the sulfonamide compounds and their use in ointments, in tetanus, in gas gangrene and in burns

DR PERRIN H LONG, Baltimore Combinations of these drugs for local use such as sulfanilamide plus sulfadiazine or sulfathiazole have to be handled much more carefully, otherwise one will get the adverse effects of the less soluble drugs I further believe that the evidence from Pearl Harbor shows that sulfanilamide by itself is an adequate chemoprophylactic agent against wound infection Sulfonamide ointments are of value in the treatment of infected wounds I don't know anything about their use in prophylaxis of wound infection, but in superficially infected wounds sulfonamide ointments are effective, and I should think that the ointment described by Dr Vella, in which there is hydrous wool fat, would be a satisfactory ointment Zinc peroxide is excellent in the treatment of anaerobic or microaerophilic infections Technically it would be difficult to use adequately in the prophylaxis of wound infection if there were large numbers of casualties As far as we know there was no tetanus in Hawaii from military casualties Gas gangrene serum has not been conclusively proved to be of value in either the prophylaxis or the therapy of clinical clostridial infection What we need for the treatment of burns is a method which every one of us can use and get good results Unfortunately no method gives good results when used by all physicians The one that comes closest in the opinion of many who are interested in burns in this country is tannic acid, but, as every one knows, that does not represent the perfect treatment

SULFONAMIDE TOXICITY AS A CAUSE OF DEATH IN NEW YORK CITY IN 1941

W D SUTLIFF, MD

Assistant Director (Pneumonia) Bureau of Laboratories
New York City Department of Health

MILTON HELPERN, MD

Assistant Medical Examiner New York City Medical
Examiners Office

GERARD GRIFFIN, MD

Consultant on Pneumonia Therapy New York City
Department of Health

AND

HERBERT BROWN, BS

Statistical Clerk New York City Department of Health
NEW YORK

It is imperative that comprehensive information on the frequency of fatal sulfonamide reactions be obtained in order that the physician may employ the sulfonamide drugs with a definite knowledge of the dangers involved in their administration To fill this need, the Pneumonia Control Division of the New York City Department of Health¹ and the Bureau of Vital Records and Statistics cooperated with the New York City Chief Medical Examiner's Office to obtain clinical records for all deaths in New York City during 1941, in which some type of sulfonamide toxicity was a factor

SOURCES OF REPORTS²

The medical examiner's certification provided the greatest proportion of useful records, namely 16 out of 19 Such certification includes a critical examination of the clinical history furnished by the physician or institution and in some cases postmortem examination Reports received by the health department without the intervention of the medical examiner provided a smaller proportion of useful records, namely 9 out of 17 In these cases either sulfonamide administration was mentioned on the death certificate but was not definitely stated as responsible for death or the case was recorded in a scientific publication A questionnaire on sulfonamide toxicity to physicians reporting pneumonia deaths during parts of April and May 1941 gave only a small number of useful reports, namely 4 out of 21 cases that were studied because serious toxic symptoms were reported on the questionnaire One of these 4 cases had been reported and certified by the medical examiner before its report by questionnaire The primary function of the questionnaire was to serve as a check on the completeness of the reporting from the two other sources

CRITERIA FOR THE DIAGNOSIS OF SULFONAMIDE TOXICITY AS A CAUSE OF DEATH

Twenty-eight cases were selected for description and analysis in this report All presented toxic reactions which developed coincident with drug administration In each case the reaction was of a type produced by sulfonamide drugs and was considered the sole or a contributory cause of death

In 13 cases, the diagnosis was as well established as present knowledge permits These include 5 cases of

Read before the Section on Practice of Medicine at the Ninety Third Annual Session of the American Medical Association Atlantic City N J June 11 1942

² Three of these cases (5 14 and 15) were described by other authors

agranulocytosis (1, 2, 3, 4 and 5) 1 case of acute hemolytic anemia (9), 2 cases of purpura hemorrhagica (11 and 12), 4 cases of crystalline urinary concretions (13, 14, 15 and 16) and 1 case of dermatitis exfoliativa

assigning a cause of death. Such cases are essential to a discussion of the incidence of deaths related to sulfonamide toxicity. Questions as to the pathogenesis of the toxic condition might be raised in 12 of the 15

TABLE 1—Cases of Fatal Sulfonamide Toxicity Reported in New York City in 1941

Patient	Age	Sex	Principal Reaction	Drugs	Total Amount Gm	Disease Treated	Cause of Death
A. Toxicity Primarily Affecting the Blood Cells and Blood Forming Organs							
1 A G	53	♂	*Agranulocytosis	Sulfanilamide	103	Infected foot (diabetic gangrene)	Agranulocytosis
2 C H	50	♂	*Agranulocytosis	Sulfanilamide (33 Gm) Sulfapyridine (510 Gm)	117	Bacterial endocarditis (Streptococcus viridans)	Agranulocytosis, bacterial endocarditis
3 L W V	63	♂	Agranulocytosis	Sulfathiazole	93	Cystitis	Agranulocytosis, prostatic hypertrophy (operation), peritonitis
4 C S	44	♀	*Agranulocytosis	Sulfanilamide (in wound 60 Gm) Sulfathiazole (24 Gm)	84	Infected operative wound cystitis	Agranulocytosis, cancer of sigmoid (operation), bronchopneumonia
5 R F	13	♂	*Agranulocytosis	Sulfanilamide (33 Gm) Sulfathiazole (Intra venous 38 Gm)	57	Rheumatic fever inactive	Agranulocytosis, septicemia Staphylococcus aureus, Pneumococcus type 3
6 A M	10	♀	Agranulocytosis	Sulfanilamide	50	Pharyngitis	Agranulocytosis, bronchopneumonia
7 F M	6	♀	Agranulocytosis	Sulfapyridine	16	Upper respiratory infection	Agranulocytosis
8 R E M	60	♀	Agranulocytosis	Sulfathiazole (170 Gm) Neoprontol (170 Gm)	1	Ion illitis	Agranulocytosis, amlopyrine 7 Gm
9 C G	43	♂	Acute hemolytic anemia, hemoglobinuria, nephrosis	Sulfanilamide	10	Infected accidental wound	Acute hemolytic anemia, hemoglobinuria, nephrosis
10 M R	45	♂	Aplastic anemia	Sulfathiazole	7	Lobar pneumonia type 14	Aplastic anemia, type 13 pneumonia, bacteremia
11 B H	66	♀	Purpura hemorrhagica	Sulfathiazole	1	Lobar pneumonia	Purpura, hemorrhagica
12 N F	60	♀	Thrombocytopenic purpura	Sulfadiazine	14	Infected operative wound	Thrombocytopenic purpura (operation), Staphylococcus aureus, sepsis
B. Toxicity Primarily Affecting the Kidney							
13 C T A	45	♀	*Crystalline urinary concretions	Sulfathiazole	3	Lobar pneumonia type 14	Renal obstruction, crystalline concretions, uremia
14 H K	60	♂	*Crystalline urinary concretions	Sulfathiazole	41	Postoperative pneumonia	Renal obstruction, crystalline concretions, uremia, bronchopneumonia
15 R N	15	♀	Crystalline urinary concretions	Sulfathiazole	150	Acute	Renal obstruction, crystalline concretions, uremia
16 C N	60	♀	*Crystalline urinary concretions	Sulfadiazine	14	Lobar pneumonia type (not confirmed)	Uremia, pyelitis, chronic cholecystitis and lithiasis
17 E C D	6	♂	Acute nephrosis	Sulfathiazole	8	Carbuncle of neck	Acute nephrosis, uremia
18 M McG	56	♀	Acute nephrosis	Sulfapyridine	14	Bronchopneumonia	Acute nephrosis, uremia
19 F R	45	♂	Azotemia	Sulfathiazole (Intravenous)	21	Postoperative pneumonia	Uremia, bilateral renal calculus, operation, peritonitis, pneumonia
20 W J D	57	♂	Azotemia	Sulfathiazole	40	Pneumonia (not confirmed)	Uremia, chronic hypertension, cardiovascular disease, pulmonary edema
21 N L	6	♂	Azotemia	Sulfadiazine	27	Bronchopneumonia	Uremia, hypertension, nephrosclerosis
22 L K	56	♀	Azotemia	Sulfapyridine	31	Bronchopneumonia	Uremia, chronic nephritis (histocopy), bronchopneumonia
23 P M	39	♀	Azotemia	Sulfapyridine	12	Pneumonia	Uremia, arteriosclerosis, nephritis
24 G B	70	♂	Azotemia	Sulfathiazole	29	Infected chronic leg ulcers	Uremia
C. Toxicity Primarily Affecting the Skin and Other Toxic Manifestations							
25 E A W	31	♀	*Dermatitis exfoliativa	Sulfapyridine	24	Gonorrheal vaginitis	Dermatitis exfoliativa
26 J M	42	♂	Dermatitis hyperpyrexia	Sulfathiazole (Intravenously 6 Gm)	70	Lobar pneumonia	Sulfathiazole toxicity, lobar pneumonia
27 R P	59	♂	Dermatitis pulmonary edema	Sulfathiazole (8 Gm) Sulfapyridine (11 Gm) (29 Gm Intravenously)	83	Bronchopneumonia	Sulfonamide toxicity, bronchopneumonia, pneumonococcosis
28 M L	11 mos	♀	Convulsions	Sulfathiazole (72 Gm) Sulfapyridine (12 Gm) (05 Gm Intravenously)	9	Bronchopneumonia	Convulsions due to intravenous administration of sodium sulfapyridine, bronchopneumonia

* Diagnosis well established

(25) In 5 of these 13 cases the toxic reaction was the sole cause of death.

The remaining 15 cases, in which the diagnoses were merely acceptable, are included in this report because they represent a reasonable application of our knowledge of sulfonamide toxicity to the difficult problem of

acceptable cases, namely 3 cases of agranulocytosis (6, 7 and 8) and 1 case of aplastic anemia (10) because blood counts were not recorded before the conditions were recognized, 2 cases of acute nephrosis (17 and 18) because this condition has not received adequate critical study, 6 cases of azotemia (19, 20, 21, 22, 23 and 24)

because no complete mechanical obstruction of the urinary tract was recognized, and in 5 of the latter because some evidence of other kidney disease was present. Questions as to whether the toxic manifestations were severe enough to cause death might be raised in 3 of the 15 acceptable cases (26, 27 and 28), in which reactions of types not heretofore described occurred in cases in which intravenous therapy was administered for pneumonia and in which the pneumonia as well as

in the seventh decade of life. The 4 exceptions were 1 infant of 11 months and 3 young adults of 13, 15 and 19 years of age. They were equally divided as to sex into 14 males and 14 females. Characteristic features of the reactions are listed in tables 1 and 2.

Types of Principal Reactions and Drugs Administered—The symptoms of toxicity affected primarily the blood cells and blood forming organs in 12 of the 28 cases (table 1, section A). Of these 8 had agranulo-

other concurrent disease were present at death. In 5 of the 15 acceptable cases the toxic reaction was considered the sole cause of death. Autopsy protocols were studied and confirmed the diagnosis in 8 of the 13 well established cases and in 4 of the 15 cases that were considered merely acceptable.

DESCRIPTION OF REACTIONS

The 28 patients presenting the diagnosis of sulfonamide toxicity associated with death were, with 4 exceptions, 31 years of age or over, the largest number being

cytosis, 1 acute hemolytic anemia, 1 aplastic anemia and 2 purpura hemorrhagica. Each of the common sulfonamide drugs used alone or in combinations with other sulfonamide drugs, accounted for one or more of these reactions. Agranulocytosis followed the administration of one drug in 4 cases, i.e., sulfanilamide in 2, sulfapyridine in 1 and sulfathiazole in 1, and agranulocytosis followed the administration of two drugs in 4 cases, in one of which sulfanilamide and sulfapyridine were administered, in 2 sulfanilamide and sulfathiazole

and in 1 azosulfamide, sulfathiazole and aminopyrine. The 1 case of acute hemolytic anemia followed sulfanilamide. One case of aplastic anemia followed sulfathiazole. Purpura followed sulfathiazole in 1 case and sulfadiazine in another.

Toxicity primarily affected the urinary tract in 12 of the 28 cases (table 1, section B). Obstruction by crystalline concretions occurred in the ureters, kidney pelvis or kidney tubules in 4 of these cases. Acute degenerative nephrotic lesions almost entirely confined to the tubular epithelium, without evidence of obstruction by crystalline concretions, were found in 2 cases. Azotemia increasing progressively to death appeared following sulfonamide drugs in 6 cases, in 5 of which some evidence of previous renal damage due to other disease was also present. Three cases of crystalline urinary concretions followed sulfathiazole administration, and 1 followed sulfadiazine. One case of acute nephrosis followed sulfapyridine, and 1 followed sulfathiazole. Two cases of azotemia followed sulfapyridine. 3 followed sulfathiazole and 1 followed sulfadiazine.

The remaining 4 of the 28 cases in which sulfonamide toxicity was diagnosed, and related to the cause of death, constitute a miscellaneous group of reactions that have been the subject of few or no reports in the medical literature. The first of these 4 patients had dermatitis exfoliativa, the second patient had acute generalized dermatitis and hyperpyrexia, the third patient developed acute generalized dermatitis and pulmonary edema. The fourth patient was an 11 month old infant girl who had convulsions and hyperpyrexia. The first patient had received sulfapyridine, the second sulfathiazole and the third and fourth both sulfapyridine and sulfathiazole. The 3 cases with acute dermatitis and fever all followed unusually large doses of the drugs, part of which was administered intravenously, and death occurred within twenty-four hours of the appearance of toxic symptoms.

No cases of death from acute liver degeneration following the use of sulfonamide drugs were reported in New York City in 1941.

In the whole series of 28 cases sulfanilamide was used in 6 cases, azosulfamide in 1, sulfapyridine in 8, sulfathiazole in 16 and sulfadiazine in 3. One drug only was used in 22 cases and two drugs in 6 cases.

Drug Dosage—There is a tendency for serious toxic reactions to follow doses of sulfonamide drugs that are greater than those usually required for therapeutic effect. Twenty of the 28 patients received 20 Gm or more of sulfonamide drugs. The dosage of sulfonamide drugs was highest in the first 6 patients with agranulocytosis, all of whom received 50 Gm or more. Drug dosage was also high in 3 patients who had reactions characterized chiefly by drug fever and rash, 2 adults who received 70 Gm or more, and an 11 month old girl who received 89 Gm. In 1 case with renal toxicity 128 Gm was given but in the remaining 11 cases with renal toxicity the drug dosage was lower, ranging from 12 to 44 Gm. In the 6 remaining cases, in 5 of which the blood was affected by the toxic reaction, and in 1 case of dermatitis exfoliativa, the dosage was even lower, ranging from 7 to 24 Gm per case.

Number of Days Elapsing Before the Development of Toxic Reactions—The number of days from the beginning of sulfonamide administration to the appear-

ance of toxic symptoms and death tended to be similar in individuals with certain reactions (table 2). Agranulocytosis in 6 cases was recognized twenty-one or more days after the drugs were begun. In the 2 remaining cases of agranulocytosis the intervals between the beginning of treatment and recognition of toxicity were very short, two and four days respectively, but in these cases blood counts were not made before treatment was begun, and the possibility that agranulocytosis was present even before drug administration should not be overlooked. Acute hemolytic anemia appeared within twenty-four hours of the first dose of sulfanilamide. Aplastic anemia and purpura hemorrhagica were recognized on the fifth or sixth day after therapy was begun. Toxicity primarily affecting the kidney was recognized at variable periods after therapy began, up to thirty-two days, most often at the end of the first week. Dermatitis exfoliativa was recognized twenty-three days after sulfonamide therapy was begun. Acute toxemia in patients receiving intravenous sulfonamide drugs appeared about the end of the second week of treatment of 3 patients.

Fatal termination followed the first symptoms of toxicity in 6 of the cases of agranulocytosis at an interval of five or six days. In the 2 remaining cases of agranulocytosis death occurred in two and twelve days respectively, after recognition of agranulocytosis. One case each of acute hemolytic anemia and aplastic anemia resulted in death ten and seventeen days respectively after they were recognized. Two cases of purpura hemorrhagica, on the other hand, had very short durations, death occurring in two days in both. Renal toxicities were variable in duration, ranging from one to nine days in all but 2 cases, in which the durations were fourteen and thirty-four days respectively. The 1 case of dermatitis exfoliativa resulted in death fifteen days after the skin reaction was first recognized. In the 3 cases of sulfonamide reactions in which the drugs were administered intravenously death occurred acutely within twenty-four hours after onset of the reactions.

Drug and Fever Skin Reactions—These alone or in combination preceded other signs of drug toxicity in 9 cases. One or both of these symptoms were present in a total of 14 of the 28 cases, in 3 of 8 cases of agranulocytosis, in 3 of 4 cases in which crystalline urinary concretions were present, in 2 cases of acute nephrosis, and in all 4 miscellaneous cases in which a cutaneous reaction or hyperpyrexia were an essential part of the principal toxic reaction. In only 2 of 6 cases of azotemia was drug fever or cutaneous reaction present. In 7 of the remaining 14 cases in which toxicity affected the blood, fever occurred which could not be distinguished from that due to the disease under treatment, while in 7 there were no sustained fever and no cutaneous reactions. When one or both of these two symptoms are attributed to drug toxicity their possible association with other serious toxic manifestations should be considered.

Diseases for Which Sulfonamide Drugs Were Administered—Pneumonia treatment was responsible for 14 of the 28 cases reported in this series. This predominance was especially pronounced in the 12 cases of toxicity affecting the kidney, in 9 of which treatment was given for pneumonia. Gonorrhea, on the other hand, was the disease under treatment in only 1 case. The infrequency of toxic reactions in the treatment of gonorrhea has been noted by others and has been

attributed to the relatively small doses of sulfonamide drug administered for gonorrhea. Other diseases for which sulfanilamide treatment was given were local infections 3 cases, upper respiratory infections 3 cases, infected surgical wounds 2 cases, bacterial endocarditis 1 case, cystitis 1 case, carbuncle 1 case, acne 1 case and rheumatic fever 1 case.

FREQUENCY OF DEATHS DUE TO SULFONAMIDE TOXICITY

Experience shows that case reporting is rarely complete. More complete reporting of sulfonamide toxicity was therefore sought by specific inquiries to physicians and hospitals reporting deaths due either to primary pneumonia or to pneumonia classified as secondary to another disease. Pneumonia was chosen as the subject of the questionnaire because treatment of pneumonia is the commonest source of reports of fatal sulfonamide toxicity. Questionnaires were sent out for 1,000 consecutive cases and filled out and returned for 993. One or more sulfonamide drugs were administered in 645 of these. Complete case records were studied for 20 that presented the most serious toxic symptoms. In 1 the diagnosis of sulfonamide toxicity was well established (11, purpura hemorrhagica), and in 3 evidence for the diagnosis of sulfonamide toxicity associated with death was acceptable (7, agranulocytosis, 22, azotemia and 23, azotemia). Four of these cases are included in the 28 cases of fatal sulfonamide toxicity. Only 1 of these 4 fatal cases of sulfonamide toxicity (7) had been reported through ordinary channels before the questionnaire was submitted. Evidence was therefore obtained that reporting by the usual methods was not complete. A rough calculation of the degree of completeness may be made by comparing the proportion of the cases of fatal sulfonamide toxicity among the pneumonia deaths the subject of questionnaire with the proportion of cases of fatal sulfonamide toxicity reported as occurring in cases of pneumonia among the estimated total number of cases in the city in which sulfonamide treatment was administered. The ratio of toxic deaths in the questionnaire was 4 in 645, or 1 death due to sulfonamide toxicity in 161 pneumonia deaths. The ratio for the city as a whole was 8 in 5,480 estimated pneumonia deaths,³ or 1 death due to sulfonamide toxicity in 685 pneumonia deaths. In one borough with the best record of case reporting, however, the ratio was 5 fatal reactions in an estimated 1,778 pneumonia deaths in cases in which sulfonamide drugs were administered, or 1 death due to sulfonamide toxicity in 356 pneumonia deaths. These calculations confirm our impression that reporting of sulfonamide deaths by the ordinary methods is incomplete but that it can be increased considerably under certain conditions.

The questionnaire also furnished additional information as to the frequency with which drugs were employed. During this period sulfathiazole was the drug most often used for the treatment of pneumonia. Sulfathiazole was given in 329, or 51 per cent, of the 645 cases, sulfapyridine in 168, or 26.1 per cent, sulfanilamide in 23, or 3.8 per cent, sulfadiazine in 18,

or 2.8 per cent, and more than one drug in 107, or 16.6 per cent. Despite the frequent use of sulfathiazole only 1 of the 4 cases of sulfonamide toxicity associated with death revealed by the questionnaire followed sulfathiazole, while 3 followed the use of sulfapyridine. It has been noted, however, that sulfathiazole was the drug most often administered in the 27 cases described. This may have been due merely to the more frequent use of sulfathiazole during this period in the treatment of disease. There is no evidence in this study that sulfathiazole is more often followed by fatal toxicity than the other commonly used sulfonamide drugs.

SUMMARY

The 28 reported cases of sulfonamide toxemia associated with death conform to one standard of diagnosis. They were reported almost entirely by ordinary methods in one year in a city in which a total of 74,553 deaths from all causes occurred, or approximately 1 fatal case of sulfonamide toxicity in every 2,571 deaths from all causes. One fatal sulfonamide reaction was reported by ordinary means among every 685 estimated pneumonia deaths. The highest frequency was found to be 1 sulfonamide death among 161 reported pneumonia deaths by supplementary inquiries on sulfonamide toxicity to physicians reporting deaths from pneumonia. Since the present fatality rate of pneumonia is in the neighborhood of 10 per cent, it may be estimated that there is as many as 1 sulfonamide death for every 1,610 pneumonia cases in which sulfonamide drugs are employed. These numbers are believed to be as near to the actual incidence of death due to sulfonamide toxicity as one may approach by ordinary methods of reporting at this time. Difficulties encountered in making positive assertions as to causes of death in such cases are illustrated by the necessity for considering the diagnosis as well established in some cases and merely acceptable in others. Such diagnostic difficulties must often deter physicians from reporting sulfonamide toxicity as a cause of death. It was therefore assumed that reporting would be incomplete, and this assumption was substantiated by the results of the questionnaire. The incidence of sulfonamide toxicity associated with death as found here is an improvement on previous data because of the relatively large numbers involved, and it is therefore useful despite its known incompleteness as a basis for discussing the present significance of sulfonamide deaths. These data will also be of value as a comparative figure for other similar studies.

COMMENT

Although few individual physicians treat enough patients with sulfonamide drugs to make the risk of fatalities approach certainty within periods of one or even several years, every physician using sulfonamide drugs runs some risk of observing such a fatality among his own patients. The serious problem presented by the combination of great therapeutic value with definite toxic hazards must be faced by the profession.

The frequency of fatal sulfonamide toxicity makes it necessary to consider the possibility of reducing their numbers. Measures are being actively sought to avoid serious toxic reactions, but so far with little success. It seems possible, however, that the use of less drug in each case would prevent the occurrence of some reac-

³ Estimated to correspond with those considered in the questionnaire as follows: 3,380 recorded primary pneumonia deaths times 2.49 equals an estimated total of 8,431 deaths in which pneumonia was the primary or contributory cause. 65 per cent of 8,431 equals 5,480, the number of pneumonia deaths in which it is estimated that sulfonamide treatment was given.

tions Emphasis on early diagnosis of susceptible infections and early treatment with resulting more rapid and more complete therapeutic effects is the most desirable method of decreasing the amount of drug needed in each case It is not advisable to change standard dosage schedules which are known to be successful, since they are based on experimental demonstration of the necessity for certain minimum blood levels of the drugs for maximum therapeutic effect

Even after the onset of toxic symptoms, measures may be taken to reduce the number of fatalities Early recognition of serious toxic symptoms, followed by prompt cessation of drug therapy, is of considerable importance Symptomatic therapy, such as transfusion in blood dyscrasias, alkalization of urine in hemoglobin nephrosis and instrumental relief of gross urinary tract obstruction may also save some patients But symptomatic therapy can be only partially successful, and some fatal toxic reactions will continue to occur It is to be hoped that biochemists will develop therapeutic agents which are less toxic or devise ways of lessening the toxic effects of present drugs

The frequency of fatal sulfonamide toxicity makes it necessary to consider whether the beneficial results of sulfonamide drug therapy are sufficient to justify the continued use of these drugs as now practiced Since low fatality rates have been shown to result from sulfonamide therapy in many infections, the changes in reported deaths from diseases for which sulfonamide drugs are now used should give some indication as to whether lives are actually being saved Striking changes have occurred in the number of reported deaths in New York City from the fourteen following infections for which sulfonamide drugs are used to treat the infection itself, to treat predisposing conditions, or to treat serious complications cerebrospinal (meningococcal) meningitis, scarlet fever, erysipelas, measles, meningitis (not meningococcal), diseases of the ear and mastoid process, pneumonia (all forms), empyema, diseases of the pharynx and tonsils, appendicitis, abortion with mention of infection, infection during childbirth and through the puerperium, phlegmon and acute abscess, and osteomyelitis and periostitis It is estimated that if the average mortality rate from these causes of 137.5 deaths per hundred thousand of population during the five years 1932 through 1936, before the introduction of sulfonamide drugs had persisted through 1941, 10,341 deaths would have occurred instead of the 4,475 reported, a difference of 5,866 deaths⁴ While the number of deaths from many of these diseases was decreasing before this period and were subject to other influences than the introduction of sulfonamide drugs, it may reasonably be assumed that some part of the decrease in each of these conditions was due to sulfonamide therapy It is safe to say that the number of lives saved by sulfonamide drugs in New York City in 1941 was very much greater than the number of deaths caused by the toxic action of these drugs

Bacterial endocarditis presents a special application of sulfonamide drug treatment, because the disease is almost invariably fatal and therefore fatalities which appear to be due to the drug are also usually considered due in part to the disease The number of recoveries resulting from drug therapy is, however, small, and it would be well to demonstrate that the number of

recoveries from sulfonamide treatment of bacterial endocarditis is greater than the number of cases in which serious terminal toxic reactions occur in evaluating drug therapy of this disease

In acute gonococcal infections, few or no lives are saved, but since 85 per cent of the cases result promptly in cure by one course of a relatively small dose of sulfathiazole, the prospect of eradicating this disease is considered well worth the few serious toxic reactions that result from sulfonamide treatment

Our present satisfactory experiences with sulfonamide treatments encourage their extension to other diseases Such extensions should be based on therapeutic trial carried out to assemble clear information as to therapeutic and toxic effects Such extension may, however, be directed toward the prevention of sequelae of the disease under treatment, the prevention of infections resulting from operative procedures, the prevention of recurrences of disease such as acute rheumatic fever or toward the cure of the carrier state for various pathogenic bacteria It is essential that such preventive use of sulfonamide drugs should be considered successful only when fatal toxic reactions are entirely avoided

This study of fatal toxic reactions following the use of sulfonamide drugs in one year in New York City presents no evidence that would modify the course that is being pursued in the routine use and in the experimental extension of the use of sulfonamide drugs The benefits derived from this course are much greater than the risk of serious toxic reactions incurred

ABSTRACT OF DISCUSSION

DR PERRIN H LONG, Baltimore Dr Sutliff and his co workers are to be congratulated because theirs is the first attempt to find out how many people have died as the result of treatment with sulfonamide compounds Some of our more pessimistic friends were not completely right, as the report shows, that sulfonamide therapy is not a leading cause of death This study brings up another question What is happening to our population from the point of view of becoming sensitized to sulfonamide drugs? Recently I reviewed many figures dealing with the incidence of sulfonamide toxicity in adults and, if one considers fever, rash, acute hemolytic anemia, leukopenia, granulocytopenia, hematuria, oliguria, azotemia, anuria and liver damage as the important toxic reactions, one finds that with sulfanilamide one gets a total of 11.9 per cent complication, with sulfapyridine 15.9 per cent, with sulfathiazole 18.6 per cent and with sulfadiazine 6.5 per cent These percentages are based on records from thousands of adults and probably are statistically correct In 1941 there were probably about 750,000 pounds of sulfapyridine produced in this country, 1,200,000 pounds of sulfanilamide and between a million and million and a half pounds of sulfathiazole A certain amount of this production was used in veterinary medicine, a small amount in dentistry and a fair amount was exported, but that still leaves a great deal of the sulfonamides for use in this country One can judge that somewhere in the neighborhood of 10 to 15 million people received one of the sulfonamide derivatives last year With this in mind, and with our knowledge of the frequency with which sensitivity to these drugs arises, it shows that these drugs should not be administered unless definite indications for their use is present, otherwise we shall gradually sensitize a large section of our population The authors stressed the question of the relation of the size of the dose to the occurrence of toxic reactions There can be no question that there is a definite relation between the amount of the drug administered to the occurrence of toxic reactions, but there is also another factor, especially with granulocytopenia, namely the time factor A survey of the literature (there are about 250

cases of granulocytopenia from sulfonamide compounds reported) shows that with but few exceptions this toxic reaction occurs after the twelfth day of treatment. That is why the total dosage often seems great. If one determines incidence in respect to time, one will find that granulocytopenia occurs most frequently between the seventeenth and the twenty-fifth day of treatment with the earliest case occurring in the first week and the latest cases occurring as late as the sixtieth or seventieth day of treatment.

DR RUSSELL L CECIL New York Dr Sutliff and his co-workers have made an important contribution to the subject of sulfonamide intoxication as a cause of death. It is clear from their figures that a great majority of the fatal reactions from sulfonamide treatment result either from damage to the kidneys or from depression of the hemopoietic system. In my experience renal damage has usually taken the form of crystalline obstruction in the pelvis or tubules, but apparently a nephrosis or even a nephritis with azotemia may also occur. We must not forget, however, that many of the infections, such as pneumonia, in which sulfonamide therapy is used, are capable of producing by themselves, considerable tubular and glomerular damage. It is quite possible, therefore, that the sulfonamides in such cases may occasionally augment an already damaged tissue. The fatalities resulting from injury to the hemopoietic system may result from granulocytopenia or less frequently from hemorrhagic purpura and aplastic or hemolytic anemia. I was particularly interested in Dr Sutliff's reference to those cases of granulocytopenia which had developed in 6 cases twenty-one or more days after the drug was begun. These delayed reactions are something we must keep in mind, and their occasional occurrence makes it necessary to watch the blood for several weeks after the drug treatment has been discontinued. It is also obvious from Dr Sutliff's study that any one of the four commonly used sulfonamides may be responsible for a fatal reaction. Toxic reactions are much less prevalent with sulfadiazine than with the other sulfonamides, but already a number of deaths have been reported from sulfadiazine therapy. Dr Norman Plummer has determined the incidence of toxic reactions in 1,000 patients treated in our wards at the New York Hospital with sulfadiazine or sodium sulfadiazine. One hundred and five of these patients showed some form of toxic manifestation, but the great majority of these were of a very mild character. Renal irritation, skin rashes and drug fever made up the greater number of the reactions, and none of these were of a serious nature. The one fatal reaction was a thrombocytopenic purpura. Strangely enough, the only fatal reaction which I have encountered in private practice was also due to hemorrhagic purpura. This occurred in a middle aged man with lobar pneumonia and followed the administration of about 40 Gm of sulfapyridine. Finland has recently reported 445 cases in which sulfadiazine therapy was employed with no deaths. His percentage of toxic reactions was about the same as that observed by Dr Plummer. Perhaps the surest way to avoid fatal toxic reactions is to use the minimum amount of drug necessary to control the infection.

The Average Doctor—Honour the physician with the honour due unto him for the uses which ye may have of him. So wrote Jesus Ben Sirach, the son of Sirach. The usefulness of the doctor, then, is his mark of distinction, and the wish to spend his life in a useful manner is probably the closest approach to altruism that most physicians achieve. There are some, undoubtedly, who hear the call to minister to humanity as a sacred duty, and if they are sincere they are worthy of special respect, but an intimate acquaintance with the medical profession leads me to believe that the average doctor has neither more nor less nobility of character than has the average decent citizen of the same breeding, environment and education, he simply happens to be more interested than are they in helping people to get well, that is his work, and he loves it but it is not his religion—Irrving, Fredrick C. Safe Deliverance, Boston Houghton Mifflin Company, 1942.

THE SODIUM SALTS OF SULFAPYRIDINE SULFATHIAZOLE AND SULFADIAZINE

THEIR CLINICAL USE BY HYPODERMOCLYSIS

FIRST LIEUTENANT GEORGE V. TAPLIN

MEDICAL CORPS, ARMY OF THE UNITED STATES

FIRST LIEUTENANT EDWARD A. CUSTER

MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

LAWRENCE E. YOUNG, MD

ROCHESTER, N. Y.

In a previous communication from this clinic¹ the use of sodium sulfapyridine by hypodermoclysis was discussed. Our purpose in this paper is to describe in more detail our experience with the subcutaneous use of the sodium salts of sulfathiazole and sulfadiazine in addition to that of sulfapyridine and to emphasize that these drugs may be administered safely and conveniently by hypodermoclysis. During the past three years the aforementioned sulfonamide compounds have been administered by this route in 160 cases of pneumonia and other conditions for which this group of drugs was indicated but in which oral administration was difficult or impossible. More recently concentrations of these drugs in the blood have been followed at frequent intervals after hypodermic administration in 19 of these cases. The results of these studies are presented here.

METHOD OF PREPARATION AND ADMINISTRATION OF SULFONAMIDE SOLUTIONS

The majority of the patients were treated with 0.5 per cent sodium sulfonamide solutions made by dissolving 5 Gm of the sodium sulfonamide in 1 liter of isotonic solution of three chlorides isotonic solution of sodium chloride or one-sixth molar sodium lactate solution. Concentrations of the sulfonamide compounds as high as 0.8 per cent were used. Isotonic solution of sodium chloride was the vehicle most commonly employed.

The solutions were prepared in one of the following ways: 1. The sodium sulfonamide was added to the vehicle and the mixture heated to the boiling point and allowed to cool to body temperature before administration. 2. The vehicle was first heated to the boiling point and allowed to cool slightly and then the drug was added. After cooling, the solution was ready for use. The first method is the more convenient but either may be used without apparent difference in blood concentration or therapeutic response.

The pH values of the sulfonamides in saline solution as determined by the Beckman apparatus were as follows: sodium sulfapyridine 10.0, sodium sulfathiazole 9.5 and sodium sulfadiazine 9.2. In spite of the decided alkalinity, these solutions caused no local reactions when injected under the skin.

The solutions described were injected into both thighs by hypodermoclysis over periods of from two to five hours. Some patients were given an initial intravenous injection of from one fifth to one third of the prepared 0.4 per cent to 0.8 per cent sulfonamide solution over a twenty to thirty minute period. The remain-

Dr N. L. Kaltreider assisted the authors in this study. Released for publication by the War Department Manuscript Board which assumes no responsibility other than censorship for the contents of this article.

ing portion of the solution was then given by hypodermoclysis

From 19 patients blood samples for sulfonamide determinations were taken, in most instances at the following intervals after treatment was started two, four, six, eight, twelve, twenty and twenty-four hours. In some instances, when indicated, a second or even a third hypodermoclysis was given. As a rule it was possible to give the drugs orally after the patient had received from 5 to 20 Gm of the sulfonamide compound subcutaneously. All blood concentrations were done by the method of Bratton and Marshall.²

BLOOD CONCENTRATION CURVES FOLLOWING HYPODERMIC ADMINISTRATION

The trend of blood concentrations after hypodermic administration of three sulfonamide compounds is illustrated in the charts. The cases selected were chosen because they illustrate the variations encountered and show the limits within which most of the curves fall.

The patients employed in this investigation were all hospitalized, and sulfonamide therapy was indicated for all of them. Most of the patients had pneumococcal pneumonia. Kidney function, as judged by urinalysis and by determinations of the blood nonprotein nitrogen was normal in most instances. The average intake was 3,000 cc in twenty-four hours.

Chart 1—The blood concentration curves following the parenteral administration of sodium sulfapyridine to 3 patients. The 2 patients whose curves are indicated by solid dots and hollow dots received an initial hypodermoclysis of 7.5 Gm and 5 Gm respectively of sodium sulfapyridine in 1,000 cc of saline solution. The patient whose curve is indicated by 'x's received an initial intravenous injection of 2 Gm of sodium sulfapyridine in 400 cc of saline solution. Immediately thereafter a hypodermoclysis of 3 Gm of sodium sulfapyridine in 600 cc of saline solution was administered. At the points indicated by a circled plus sign a second hypodermoclysis of 1,000 cc was given to each patient. The concentration of the second clysis was the same as that previously given.

When sulfapyridine was employed the maximum blood concentration was reached six hours after the first clysis was started (chart 1). This maximal value varied between 4 and 5.6 mg per hundred cubic centimeters. No obvious relationship was apparent between the dosage and the type of blood concentration curve. The renal function was normal and the fluid intake and output were comparable for each of 3 patients. From twelve to sixteen hours after the first subcutaneous dose was started the blood concentration decreased rapidly. At the end of this interval a second clysis was started. The blood concentration curves following the second hypodermoclysis showed a summation, the second series of values being higher than the first, but they followed the same pattern.

Among the patients receiving sodium sulfathiazole the maximum concentration was attained in from five to eight hours after the first hypodermoclysis (chart 2).

Approximately the same interval elapsed before the maximum concentration was reached after the second subcutaneous injection. The highest concentrations varied between 3 and 12.4 mg per hundred cubic centimeters. As in the group of patients treated with sulfapyridine, it was impossible to correlate accurately the

Chart 2—The blood concentration curves after parenteral administration of sodium sulfathiazole to 4 patients. The 2 patients whose curves are indicated by 'x's and small solid dots received an initial intravenous dose of 1 Gm of sodium sulfathiazole in 200 cc of saline solution. This was followed immediately by a hypodermoclysis of 800 cc of the same 0.5 per cent solution. The 2 patients whose curves are indicated by hollow dots and large solid dots received hypodermoclysis initially of 1,000 cc of 0.75 per cent and 0.8 per cent sodium sulfathiazole in saline solution respectively. At the points indicated by a circled plus sign 3 patients received second hypodermoclyses of 1,000 cc. Each of the latter doses corresponded in strength to that previously administered to each patient.

blood concentration with the dosage, fluid balance and renal function. Likewise as in the group of sulfapyridine treated patients the optimum time for a second hypodermoclysis was from twelve to sixteen hours after the first subcutaneous dose. The blood concentration curves after the second injection followed a pattern similar to that observed in patients treated with sulfapyridine.

The maximum concentrations of sulfadiazine in the blood after hypodermic injection varied from 4.5 to 16 mg per hundred cubic centimeters (chart 3). These values were reached in from four to eight hours after the administration was started. The optimum time for giving the second hypodermoclysis was twenty to thirty hours after the first had been started. The results obtained in this group of patients also illustrate the

Chart 3—The blood concentration curves after the parenteral administration of sodium sulfadiazine to 3 patients. Each of these patients received an initial intravenous dose of 200 cc of 0.5 per cent sodium sulfadiazine in saline solution after which 800 cc of the same solution was given as a hypodermoclysis. At the points indicated by a circled plus sign each patient received a second hypodermoclysis of 1,000 cc of the 0.5 per cent sodium sulfadiazine solution. One patient received a third hypodermoclysis of the same strength and amount.

lack of correlation between dosage, renal function, fluid balance and the pattern of the blood concentration curve. The patient having the lowest blood concentration values had a blood nonprotein nitrogen of 83 mg per

² Bratton A. C. and Marshall E. K., Jr. New Coupling Component for Sulfanilamide Determination, *J. Biol. Chem.* 128: 537 (May) 1939.

hundred cubic centimeters, while the patient showing the highest blood concentration had apparently normal renal function. In both cases the fluid intake and output were adequate and comparable. In most instances summation was noted in the curves for the second and third hypodermoclyses of sodium sulfadiazine, although there is little evidence of this in the curves selected for illustration in chart 3.

COMMENT

From the data presented it is apparent that there are wide variations in the blood concentration curves of different patients following the hypodermic administration of each of the sulfonamide solutions studied. Plummer and Wheeler³ noted this unpredictable variation in the blood concentration of sodium sulfadiazine when repeated doses were given intravenously. Because of the decided variations in the blood concentrations of the sulfonamide compound attained in different patients following the subcutaneous injections of these drugs, one can neither adopt a standard dosage nor give subsequent doses at arbitrarily fixed intervals. If such a routine was followed 1 patient might receive a toxic dose while another might receive an inadequate one. In order to circumvent these difficulties it is necessary to guide treatment by following the blood concentrations at frequent intervals. By so doing one may determine the pattern of the blood concentration curve for each patient and give subsequent doses at an optimal time, also the dosage may be altered to suit the case in question.

An idea of the pattern of the blood concentration curve may be obtained by determining blood sulfonamide levels between four and eight hours and again between fourteen and eighteen hours after treatment has been started. Subsequent treatment may be guided by the use of these two determinations.

In general, it has been found necessary to give the following approximate amounts per thousand cubic centimeter hypodermoclysis to achieve adequate blood concentrations: sulfathiazole 7.5 to 8 Gm (the blood concentrations may be low even with this dosage), sulfapyridine 5 to 7 Gm and sulfadiazine 5 Gm. In general, the blood concentrations were higher and more prolonged after the use of sulfadiazine subcutaneously than after the use of the other sulfonamide compounds. This difference in the metabolism of sulfadiazine conforms to that noted by others.⁴

It is apparent that the intravenous doses given to several of the patients included here were too small to achieve an immediate high blood concentration. The intravenous doses in the amounts used caused little appreciable difference in the blood concentration curves as compared with those obtained following initial subcutaneous doses. Hence, if one desires to obtain an immediate high blood concentration a larger intravenous dose must be given than was used in this study.

No attempt has been made in this study to evaluate the therapeutic effect of these drugs when given subcutaneously. However, the impression was gained that this route of administration gives results comparable to those achieved by oral administration.

This paper is not an attempt to promote the subcutaneous mode of administration when the drugs can be

given orally. Most patients can and should be treated by the oral mode of administration. However it is felt that giving the drugs by hypodermic injection is a great convenience and gives satisfactory results for patients who are unable to take the sulfonamides by mouth for one reason or another—such as an unfavorable mental state, persistent vomiting and sometimes after an operation.

CONCLUSION

1 The sodium salts of sulfapyridine, sulfathiazole and sulfadiazine may be conveniently and safely administered subcutaneously when the patient cannot take the drugs orally. The subcutaneous administration of the sodium sulfonamides to 160 patients caused no local reactions.

2 These drugs may be given subcutaneously in concentrations of from 0.4 per cent to 0.8 per cent in isotonic solution of three chlorides isotonic solution of sodium chloride or one-sixth molar sodium lactate solution.

3 Decided variations in the blood concentrations of the sodium sulfonamides were encountered when given by hypodermoclysis. These values were not predictable. Treatment must therefore be based on the blood concentrations encountered for each individual patient.

4 Sodium sulfadiazine was the most convenient drug to use hypodermically. A 1000 cc hypodermoclysis containing 5 Gm of this drug usually gave satisfactory blood concentrations for about twenty hours.

AN OUTBREAK OF STREPTOCOCCIC SEPTIC SORE THROAT IN AN ARMY CAMP

CLINICAL AND EPIDEMIOLOGIC OBSERVATIONS

ARTHUR L. BLOOMFIELD, M.D.

AND

LOWELL A. RANTZ, M.D.

Consultants to the Secretary of War

SAN FRANCISCO

This report of an outbreak of streptococcic sore throat in an army camp is made because there were clinical and epidemiologic features of unusual interest.

BACKGROUND

The outbreak occurred on June 17, 1942 and the next succeeding few days in a Western army camp. The camp is an assembly center for troops coming from various parts of the country. It is situated in a flat area, the weather is hot and dry in June and ordinarily there is no streptococcic sore throat during this season. At the time of the outbreak the camp was still partly under construction.

THE OUTBREAK

The outbreak began with explosive suddenness at a time when there was no illness in the camp. There were, however, a number of men who had had "tonsillitis" at other establishments within the past few weeks before coming to this camp. The number of men reporting sick each day is shown in table 1.

All the cases occurred in the personnel of a single unit (area 1) of some 3000 men. Thus the incidence was approximately 10 per cent. However it is not cer-

Lieutenant Colonel Culpepper and other medical officers gave the authors assistance and advice.

This investigation was aided through the Commission on Hemolytic Streptococcal Infections, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Service Office of the Surgeon General, United States Army.

tain that all the members of the unit were exposed, so that the exact morbidity in relation to ingestion of streptococci is not known.

GROSS EPIDEMIOLOGIC FEATURES

The explosiveness of the outbreak with the great number of cases on the first day without reports of sore throats during the preceding week suggested ingestion

of streptococci in large numbers. The fact that each area has its own kitchen and mess halls and that the men were all from one area is in harmony with this idea. However, milk, which is the commonest vehicle for infection in outbreaks of this sort, seemed to be ruled out, since it was obtained in individual pasteurized half-pint bottles from a high class dairy. No other article of food could be positively incriminated but it was our impression that some dish which a large number of men ate had become highly contaminated with hemolytic streptococci.

There was no evidence of spread of the infection from person to person. Not a single case occurred among the medical officers or hospital personnel even though they were intensively exposed and were unable to use the usual isolation precautions because the hospital was not yet fully equipped at the time of the outbreak. It seems probable that the streptococci causing the outbreak were relatively "avirulent" and produced disease only because they were ingested in huge numbers. Further evidence to this effect will be presented later.

CLINICAL FEATURES

The men came down abruptly with sore throat and malaise and in the more severe cases with chills and high fever. On the whole, very few of the patients seemed dangerously ill, and there were no deaths. The appearance of the throat was typical of acute streptococcal tonsillitis. The tonsils were swollen, in some cases to huge proportions, and they were stippled with white patches of exudate. In those whose tonsils had been removed there was inflammation of the bits of lymphadenoid tissue in the pharynx and tonsillar fossae. In approximately one fourth of the cases there was a classic scarlatinal rash which ran the usual course, with eventual desquamation of the glove type. In other patients there were only traces of the exanthem, and in the majority a rash was not seen at any time. After a few days of fever, sore throat resolved and

general symptoms quickly cleared. Aside from a few insignificant local lesions to be mentioned presently there were none of the usual complications of outbreaks of septic sore throat—no general sepsis, suppurative adenitis or peritonitis.

COMPLICATIONS

As already stated, there were no deaths or serious septic complications. The medical officers at the camp furnished the data given in table 2.

These figures were supplemented by our own study of 127 men. Among them there was 1 who gave a story of "abscess in the throat" bursting during the acute attack but with no further trouble. Two men said that about a week after onset they had a running ear (not opened), but there was no drainage at the time of our examination two weeks later.

To sum it up, then, there were to all intents and purposes no septic complications in this outbreak. Whether this unusual state of affairs was due to sulfonamide therapy or to infection with an organism of "low virulence" is not clear.

TABLE 3—Arthralgic Symptoms in Convalescents

Series No.	Severity of Original Attack	Symptoms	Objective Findings July 9	Condition of Throat July 9
119	Moderate	About a week after onset had vague aches and pains—fairly bad—lasted 3 days	None	Throat clear
48	Severe	About a week after onset relapsed with a little fever, left knee hurt for 1 day	None	Throat clear, small tonsils
98	Mild	Headache and pain in back ever since onset, left knee hurt for 1 day	None	Throat clear, tonsils out
4	Moderate	Well for a week—then back ached for 2 days, feels well again now	None	Small clean tonsils, large glands at angles of jaws
8	Mild	A little pain in left knee today	None	Throat clear, small tonsils
93	Severe	About 1 week ago right elbow was sore for a day, not since and all right now	None	Large congested tonsils
10	Moderate	Feels stiff and tired each morning	None	Throat clear
112	Mild	Well until today, this morning nausea, malaise and knees ache, temperature subnormal	None	Throat clear, tonsils small and clean
118	Severe	Feels tired, has no energy, has aching throughout back	None	Tonsils out
116	Severe	Aching of lower part of back since onset—not bad	None	Large clean tonsils
113	Severe	Left fairly well until today, this morning had temperature of 100 F. and has pain in neck and over eyes	None	Huge congested tonsils
109	Moderate	A few days ago both wrists were sore for a few days, well now	None	Large congested tonsils
114	Mild	Muscles around left knee have been sore	None	Throat clear
21	Mild	Has ached all over ever since onset, not specially in joints	None	Throat clear

SEQUELAE

An outbreak of this sort under highly uniform conditions seemed to offer an especially good opportunity for the study of sequelae. We interviewed and examined 127 men on July 9, twenty-two days after onset.

Septic Sequelae—There were no late septic complications.

Adenitis—There were no instances of general adenitis, although a good many of the men still had

enlarged glands at the angle of the jaw, probably associated with persisting tonsillar infection

Arthritis, Arthralgia and Rheumatic Fever—The view is widely held that rheumatic fever may be "activated" by acute hemolytic streptococcal infection.¹ Some observers, however, are not certain that the arthralgia or mild arthritis which often is noted about three weeks after an attack of septic sore throat is true rheumatic fever. It is not our purpose to enter into this discussion now, we shall merely report findings. Fourteen men, or 11 per cent of those interrogated, gave a story of mild symptoms which perhaps fall into this group. The details are given in table 3. It is seen that disability was slight and that there were no objective findings in any case at the time of our examination. So that while the significance of these phenomena is not entirely clear, we are not inclined to interpret them as rheumatic fever but rather to class them with the mild aches and pains which are noted during convalescence from any acute infectious disease and which are not followed by further trouble.

Blood Pressure—The readings were made with the subject sitting. With a very few exceptions the men were still in the hospital although ambulatory. The temperature of the room was high and the humidity low. The conditions were such as to promote low rather than high blood pressure. We had no previous control observations. Whenever the reading seemed high it was carefully checked. The results are given in table 4. One gets the impression that there are more men with slight hypertension than one would expect in a group of this sort.

The Urine—Here was an unusual opportunity to make careful studies of urinary sediment in a large group of young men who had been subjected simultaneously to a highly specific type of streptococcal infection. Through the cooperation of the medical officers it was possible to collect 59 specimens, which were concentrated according to the specifications of Addis.² Specimens of urine were obtained as well from most of the other men in the group. We are indebted to Dr. Thomas Addis for personally examining many of these. It may be said that the quantitative studies of the urinary sediment were conspicuously negative. In no case were there any findings to suggest the presence of nephritis. The few hyaline and granular casts, the occasional red blood cells and white and epithelial cells were within the normal limits laid down by Addis.² In case 48 there was a slight proteinuria which we had no chance to investigate further. This outbreak was followed by no case of clinical nephritis and three weeks after onset there were no urinary findings to indicate renal injury. This is not entirely in accord with the observations of Lyttle,³ but agrees with our previous experience that, whereas acute nephritis is often preceded by streptococcal sore throat, only an occasional case of septic sore throat is followed by nephritis.

The Local Condition of the Throat—Following a streptococcal septic sore throat it is often observed that the tonsils remain large and have a succulent congested appearance for a considerable time before they shrink to their previous proportions. At the time of our

investigation 29, or 23 per cent of the group examined still had tonsils which were definitely congested and obviously had not returned to their usual state although only 2 men complained of dryness and irritation on swallowing.

Convalescence and General Well-Being—Tonsillitis is usually considered a mild disease which entails no great disability. The men in this study were carefully interrogated three weeks after onset as to their general strength and well-being. Ninety or 71 $\frac{1}{2}$ per cent still felt below par generally, tired easily and did not consider themselves ready for duty. Seven or 5.5 per cent, were definitely unwell with great fatigue on slight effort, definite lack of well-being or vague aches and pains. No significant difference was noted between men who had had a rash ("scarlet fever") and those without rash. It is clear, then, that after any variety of streptococcal septic sore throat full recovery in the sense of restoration of physical fitness may often take more than three weeks, a fact which we do not believe is fully appreciated by physicians.

BACTERIOLOGIC FINDINGS AND CLINICAL INTERPRETATION

Throat cultures taken on June 20 at the height of the outbreak from a generous random sample of sick men including patients both with and without rash in

various wards all showed group A hemolytic streptococci in large numbers. These turned out in every case to be of the same Griffith subtype, namely type 15. This furnishes final proof of a single source of infection, especially as this type has been uncommon in the region and was found by Rantz⁴ only seven times among 260 strains.

At this point a digression on the clinical interpretation of the cases with and without scarlatinal rash is necessary, since there is still confusion in the minds of some as to this matter. Briefly, both clinical "tonsillitis" and clinical "scarlet fever" are now known to be specific hemolytic streptococcus infections of the tonsils and lymphadenoid tissue in the pharynx. Certain strains of streptococci produce a soluble toxin which in nonimmune people causes the scarlatinal rash. Absorption of this "rash toxin" is followed by antitoxic immunity to its effects,⁵ hence if a person who has had

"scarlet fever" is later reinfectd with the same organism he may have no rash but only what is ordinarily called tonsillitis.⁹ These relations, which explain the paradox of permanent immunity following one attack of "scarlet fever" with susceptibility of the same person to frequent attacks of "tonsillitis," are diagrammed in table 5

One may raise the question of whether the use of the term "scarlet fever" with the implication of a fundamental difference from acute "tonsillitis" does not serve to maintain confusion and diagnostic quibbling. The entire group should perhaps be referred to as streptococcic septic sore throat (with or without associated scarlatinal rash), and the same rules for isolation and quarantine should hold for all. Health departments that quarantine "scarlet fever" but not "tonsillitis" show complete lack of understanding of the subject.

This position was fully supported by the present study. Among 77 men of whom we had a definite record, 52 had no rash and 25 did have a rash. Eleven among the 77 gave a history of scarlet fever in the past, they were all in the group who had no rash now. Statistical analysis shows only about one chance in a hundred of this finding not being significant. Furthermore, since the same strain of streptococcus was responsible for all the cases, it is clear that absence of

TABLE 5—Diagram of Immune Status of Persons to Infecting Streptococcus

Infecting Streptococcus	Immune Status of Infected Person	Clinical Result
Produces rash toxin in the patient	Nonimmune to rash toxin Immune to rash toxin	Scarlet fever Tonsillitis
Does not produce rash toxin in the patient	Nonimmune to rash toxin Immune to rash toxin	Tonsillitis Tonsillitis

rash must be explained by immunity to "rash toxin," unless one assumes that the organisms unaccountably failed to produce erythrogenic toxin in certain persons.

Finally, there was no relation between presence or absence of rash and severity of the disease or incidence of complications. This is an important observation, since the question of whether the so-called scarlet fever toxin produces clinical effects other than the rash and whether antitoxin does more than neutralize the rash has never been finally settled. The Dicks, in the early days of the subject,⁹ pointed out that their toxin when injected into susceptible human beings produced not only rash but nausea, vomiting, malaise and fever as well. Trask,¹⁰ on the other hand, showed that the clinical severity of the attack did not parallel the amount of "toxin" in the blood serum, finally, the highly purified "erythrogenic" toxin recently isolated by Stock and his associates¹¹ by electrophoretic methods in such concentrations that there were 100 to 150 million skin test doses per milligram of the material has not been yet tried out for systemic effects.

At any rate, there was no clinical indication in the present outbreak that the patients with rash were suffering from any other symptoms not equally present in the men without rash.

RELATION OF TONSILS TO INCIDENCE OF SEPTIC SORE THROAT

It is well known that tonsillectomy confers a high degree of protection against acute streptococcic septic sore throat. Bloomfield and Felty⁶ found in the case of an institutional group of 179 persons that among 77 without tonsils 6, or 7.8 per cent, had septic sore throat whereas during the same season among 102 whose tonsils had not been removed 27, or 26.5 per cent, had attacks. Only 6 of 33 cases, or 18 per cent, occurred in persons who had had a tonsillectomy. In the present outbreak we unfortunately have no data on the number in the whole unit with and without tonsils. However, among a group of 127 men whom we examined the condition occurred in only 20, or 16 per cent, who had had a tonsillectomy.

PERSISTENCE OF STREPTOCOCCI IN TONSILS DURING CONVALESCENCE IN RELATION TO CASES

During the acute stages of septic sore throat hemolytic streptococci are obtained in huge numbers from the surface of the tonsils and pharynx. In convalescence fewer colonies are isolated from the pharynx, although many can still be recovered from the surface of the tonsils. After a variable number of weeks, surface swabs may no longer yield any hemolytic streptococci, but cultures of material aspirated from tonsillar cysts show that the organisms persist in the depths of the lymphadenoid tissue.⁷

On July 9, approximately three weeks after onset and just before discharge, we took cultures from 36 convalescents. Of these 19, or 53 per cent, yielded hemolytic streptococci from surface swabs. In every case but 1 the organisms were of the same type (Griffith type 15) as those obtained during the acute stage of the disease. The 1 exception was a type 8. It can be concluded, therefore, that when the convalescents were discharged to barracks approximately one half were carriers. In spite of contact with the other men only 1 further case of septic sore throat was reported, on July 7. A culture taken from this man yielded hemolytic streptococci (Griffith type 15), so that he was undoubtedly a "return" case.

A good deal of work has been done recently on the Griffith subtyping of streptococci recovered from the same patient during the acute stages of septic sore throat and later on during convalescence. Some workers have found striking changes in the streptococcic flora of the throat almost from day to day.¹² Furthermore, it has been pointed out that the complications or sequelae which occur in the second or third week after scarlet fever or septic sore throat often seem to be due to a streptococcus of different type from that originally isolated during the acute attack.¹³ Some of the work that has been reported is open to criticism on technical grounds, but in the main it is probably correct. It is therefore of note that in the present outbreak cultures made after three weeks showed either the original type of streptococcus (Griffith type 15), with the exception of 1 case, or no hemolytic streptococci at all. The question may be raised (but cannot be answered now) whether the absence of secondary infection with other types of streptococci is to be correlated with the lack of complications in our group.

¹³ Allison V. D. and Brown, W. A. Reinfection as a Cause of Complications and Relapses in Scarlet Fever. Wards. J. Hyg. 37: 153 (April) 1937.

It is of great interest that the introduction of large numbers of convalescent carriers into the uninfected group was not followed by more "return" cases, but this is exactly what one would expect on the basis of knowledge of "normal" hemolytic streptococcus parasitism in the throats of healthy persons. It has been shown, first, that under ordinary conditions a person does not become a contact carrier without going through a clinical attack of tonsillitis,¹⁴ and second, that acquisition of disease from a convalescent carrier, again under ordinary conditions of parasitism, occurs only if there is a very high degree of intimate contact.¹⁵ Furthermore, to be infected the person will usually not be a carrier and he must have a low natural resistance to hemolytic streptococcus infection.⁶ These considerations are of course altered under conditions of true epidemic spread of streptococci such as occurred in the Army camps in 1918 following measles and influenza.

We are now in a position to interpret the present outbreak. It was clearly not an epidemic in the sense of disease occurring by spread from man to man but rather a mass infection of the entire group from a common source. The failure of contacts to acquire sore throat suggests that the organism was not highly "virulent" and that infection was the result of ingestion of huge doses of organisms. This view is finally confirmed by the fact that when large numbers of convalescent carriers were returned into the general group only 1 case of septic sore throat resulted. In other words, a "normal" state of streptococcal parasitism existed of such a sort that intensive contact with carriers would have been necessary before further disease could be produced. There was no tendency to those obscure upsets of immunologic balance which lead to epidemic spread of streptococci through a group by person to person passage with high incidence of infection.

THERAPY AND EFFECTS

Treatment consisted of rest in bed, general measures and the sulfonamides. We are unable to draw definite conclusions as to the efficacy of the sulfonamide therapy. Whether the extraordinary lack of complications and the generally mild course of the disease is to be attributed to the drugs cannot be stated.¹⁶ It should be noted, however, that the sulfonamides have not been found by others to be highly effective in this type of streptococcal infection.¹⁷

CONCLUSIONS

1 A violent outbreak of septic sore throat which occurred in an Army camp was shown to be due to mass infection with hemolytic streptococcus Griffith type 15, a rare organism in the locality in which it occurred.

2 The contaminated article of food was not determined, but milk seemed ruled out as a source of infection.

3 An unusual feature of such a violent outbreak was the absence of complications. There were no deaths.

4 Sulfonamide therapy may have played a part in producing the mild clinical course.

Brucellosis of man, or undulant fever, is nearly always of sporadic occurrence. Animals chiefly concerned in the spread of infection are the cow, the hog and the goat. Organisms ordinarily causing infectious (contagious) abortion in these animals are respectively the bovine (*Brucella abortus*), the porcine (*Brucella suis*) and the caprine (*Brucella melitensis*) strains of *Brucella*. Infection in the cow is also known as Bang's disease and in the hog as Traub's disease. Although the possibility of occurrence of infection traceable to the goat needs to be kept in mind, the bovine and porcine strains of *Brucella* are probably the main offenders in most areas of the United States.

Main modes of conveyance of brucellosis to man are (1) through direct contact with infected animals or their abortion products and (2) through use of raw dairy products from infected sources. Brucellosis may occur in epidemic form when raw milk is consumed from cattle infected with a porcine strain of *Brucella* or a highly virulent strain of the bovine variety.

In animal inoculation work at the State Hygienic Laboratory, wide variation has been noted in the virulence of *brucella* strains as isolated from animal and human sources. Difference in virulence may help to account for the varied number of cases which occur among persons using a contaminated raw milk supply or having special forms of contact with infected animals.

In 1929 Farbar and Mathews¹ reported a milk borne outbreak of brucellosis (26 cases) and found that infection was caused by *Brucella abortus*. The agglutination test for Bang's disease proved positive in 7 of 23 dairy cows. *Brucella abortus* was isolated from the milk of 3 of the cows. Huddleson identified the *brucella* strain as of bovine origin.

A milk borne epidemic, comprising 30 cases and caused by *Brucella suis*, occurred in Council Bluffs, Pottawattamie County, Iowa, in 1933; this outbreak was

¹ Farbar Marion E. and Mathews Frank P. An Epidemic of Undulant Fever with a Study of the Associated Milk Supply. *Ann. Int. Med.* 2: 875-880 (March) 1929.

"scarlet fever" is later reinfectd with the same organism he may have no rash but only what is ordinarily called tonsillitis.⁹ These relations, which explain the paradox of permanent immunity following one attack of "scarlet fever" with susceptibility of the same person to frequent attacks of "tonsillitis," are diagrammed in table 5.

One may raise the question of whether the use of the term "scarlet fever" with the implication of a fundamental difference from acute "tonsillitis" does not serve to maintain confusion and diagnostic quibbling. The entire group should perhaps be referred to as streptococcic septic sore throat (with or without associated scarlatinal rash), and the same rules for isolation and quarantine should hold for all. Health departments that quarantine "scarlet fever" but not "tonsillitis" show complete lack of understanding of the subject.

This position was fully supported by the present study. Among 77 men of whom we had a definite record, 52 had no rash and 25 did have a rash. Eleven among the 77 gave a history of scarlet fever in the past, they were all in the group who had no rash now. Statistical analysis shows only about one chance in a hundred of this finding not being significant. Furthermore, since the same strain of streptococcus was responsible for all the cases, it is clear that absence of

TABLE 5—Diagram of Immune Status of Persons to Infecting Streptococcus

Infecting Streptococcus	Immune Status of Infected Person	Client's Illness
Produces rash toxin in the patient	Nonimmune to rash toxin	Scarlet fever
	Immune to rash toxin	Tonsillitis
Does not produce rash toxin in the patient	Nonimmune to rash toxin	Tonsillitis
	Immune to rash toxin	Tonsillitis

rash must be explained by immunity to "rash toxin," unless one assumes that the organisms unaccountably failed to produce erythrogenic toxin in certain persons.

Finally, there was no relation between presence or absence of rash and severity of the disease or incidence of complications. This is an important observation, since the question of whether the so-called scarlet fever toxin produces clinical effects other than the rash and whether antitoxin does more than neutralize the rash has never been finally settled. The Dicks, in the early days of the subject,⁶ pointed out that their toxin when injected into susceptible human beings produced not only rash but nausea, vomiting, malaise and fever as well. Trask,¹⁰ on the other hand, showed that the clinical severity of the attack did not parallel the amount of "toxin" in the blood serum, finally, the highly purified "erythrogenic" toxin recently isolated by Stock and his associates¹¹ by electrophoretic methods in such concentrations that there were 100 to 150 million skin test doses per milligram of the material has not been yet tried out for systemic effects.

At any rate, there was no clinical indication in the present outbreak that the patients with rash were suffering from any other symptoms not equally present in the men without rash.

RELATION OF TONSILS TO INCIDENCE OF SEPTIC SORE THROAT

It is well known that tonsillectomy confers a high degree of protection against acute streptococcic septic sore throat. Bloomfield and Felty⁵ found in the case of an institutional group of 179 persons that among 77 without tonsils 6, or 7.8 per cent, had septic sore throat whereas during the same season among 102 whose tonsils had not been removed 27, or 26.5 per cent, had attacks. Only 6 of 33 cases, or 18 per cent, occurred in persons who had had a tonsillectomy. In the present outbreak we unfortunately have no data on the number in the whole unit with and without tonsils. However, among a group of 127 men whom we examined the condition occurred in only 20, or 16 per cent, who had had a tonsillectomy.

PERSISTENCE OF STREPTOCOCCI IN TONSILS DURING CONVALESCENCE IN RELATION TO CASES

During the acute stages of septic sore throat hemolytic streptococci are obtained in huge numbers from the surface of the tonsils and pharynx. In convalescence fewer colonies are isolated from the pharynx although many can still be recovered from the surface of the tonsils. After a variable number of weeks, surface swabs may no longer yield any hemolytic streptococci but cultures of material aspirated from tonsillar cysts show that the organisms persist in the depths of the lymphadenoid tissue.

On July 9, approximately three weeks after onset and just before discharge, we took cultures from 36 convalescents. Of these, 19 or 53 per cent, yielded hemolytic streptococci from surface swabs. In every case but 1 the organisms were of the same type (Griffith type 15) as those obtained during the acute stage of the disease. The 1 exception was a type 8. It can be concluded, therefore that when the convalescents were discharged to barracks approximately one half were carriers. In spite of contact with the other men only 1 further case of septic sore throat was reported, on July 7. A culture taken from this man yielded hemolytic streptococci (Griffith type 15), so that he was undoubtedly a "return" case.

A good deal of work has been done recently on the Griffith subtyping of streptococci recovered from the same patient during the acute stages of septic sore throat and later on during convalescence. Some workers have found striking changes in the streptococcic flora of the throat almost from day to day.¹² Furthermore, it has been pointed out that the complications or sequelae which occur in the second or third week after scarlet fever or septic sore throat often seem to be due to a streptococcus of different type from that originally isolated during the acute attack.¹³ Some of the work that has been reported is open to criticism on technical grounds, but in the main it is probably correct. It is therefore of note that in the present outbreak cultures made after three weeks showed either the original type of streptococcus (Griffith type 15), with the exception of 1 case, or no hemolytic streptococci at all. The question may be raised (but cannot be answered now) whether the absence of secondary infection with other types of streptococci is to be correlated with the lack of complications in our group.

It is of great interest that the introduction of large numbers of convalescent carriers into the uninfected group was not followed by more "return" cases, but this is exactly what one would expect on the basis of knowledge of "normal" hemolytic streptococcus parasitism in the throats of healthy persons. It has been shown, first, that under ordinary conditions a person does not become a contact carrier without going through a clinical attack of tonsillitis,¹⁴ and second, that acquisition of disease from a convalescent carrier, again under ordinary conditions of parasitism, occurs only if there is a very high degree of intimate contact.¹⁵ Furthermore, to be infected the person will usually not be a carrier and he must have a low natural resistance to hemolytic streptococcus infection.⁵ These considerations are of course altered under conditions of true epidemic spread of streptococci such as occurred in the Army camps in 1918 following measles and influenza.

We are now in a position to interpret the present outbreak. It was clearly not an epidemic in the sense of disease occurring by spread from man to man but rather a mass infection of the entire group from a common source. The failure of contacts to acquire sore throat suggests that the organism was not highly "virulent" and that infection was the result of ingestion of huge doses of organisms. This view is finally confirmed by the fact that when large numbers of convalescent carriers were returned into the general group only 1 case of septic sore throat resulted. In other words, a "normal" state of streptococcal parasitism existed of such a sort that intensive contact with carriers would have been necessary before further disease could be produced. There was no tendency to those obscure upsets of immunologic balance which lead to epidemic spread of streptococci through a group by person to person passage with high incidence of infection.

THERAPY AND EFFECTS

Treatment consisted of rest in bed, general measures and the sulfonamides. We are unable to draw definite conclusions as to the efficacy of the sulfonamide therapy. Whether the extraordinary lack of complications and the generally mild course of the disease is to be attributed to the drugs cannot be stated.¹⁶ It should be noted, however, that the sulfonamides have not been found by others to be highly effective in this type of streptococcal infection.¹⁷

CONCLUSIONS

1 A violent outbreak of septic sore throat which occurred in an Army camp was shown to be due to mass infection with hemolytic streptococcus Griffith type 15, a rare organism in the locality in which it occurred.

2 The contaminated article of food was not determined, but milk seemed ruled out as a source of infection.

3 An unusual feature of such a violent outbreak was the absence of complications. There were no deaths.

4 Sulfonamide therapy may have played a part in producing the mild clinical course.

Brucellosis of man, or undulant fever, is nearly always of sporadic occurrence. Animals chiefly concerned in the spread of infection are the cow, the hog and the goat. Organisms ordinarily causing infectious (contagious) abortion in these animals are respectively the bovine (*Brucella abortus*), the porcine (*Brucella suis*) and the caprine (*Brucella melitensis*) strains of *Brucella*. Infection in the cow is also known as Bang's disease and in the hog as Traub's disease. Although the possibility of occurrence of infection traceable to the goat needs to be kept in mind, the bovine and porcine strains of *Brucella* are probably the main offenders in most areas of the United States.

Main modes of conveyance of brucellosis to man are (1) through direct contact with infected animals or their abortion products and (2) through use of raw dairy products from infected sources. Brucellosis may occur in epidemic form when raw milk is consumed from cattle infected with a porcine strain of *Brucella* or a highly virulent strain of the bovine variety.

In animal inoculation work at the State Hygienic Laboratory, wide variation has been noted in the virulence of *brucella* strains as isolated from animal and human sources. Difference in virulence may help to account for the varied number of cases which occur among persons using a contaminated raw milk supply or having special forms of contact with infected animals.

In 1929 Farbar and Mathews¹ reported a milk borne outbreak of brucellosis (26 cases) and found that infection was caused by *Brucella abortus*. The agglutination test for Bang's disease proved positive in 7 of 23 dairy cows. *Brucella abortus* was isolated from the milk of 3 of the cows. Huddleson identified the *brucella* strain as of bovine origin.

A milk borne epidemic, comprising 30 cases and caused by *Brucella suis*, occurred in Council Bluffs, Pottawattamie County, Iowa, in 1933, this outbreak was

1 Farbar Marion E. and Mathews Frank P. An Epidemic of Undulant Fever with a Study of the Associated Milk Supply. *Ann. Int. Med.* 2: 875-880 (March) 1929.

reported by Beattie and Rice² *Brucella suis* was isolated from the milk of a reacting dairy cow and from the blood of 6 patients

In 1934-1935 a brucellosis outbreak occurred in an institution of elderly persons in Connecticut. The report by Horning³ states that 14 cases developed in a group of 305 inmates and 81 employees. Among 3 fatal cases, blood cultures of 2 and culture of an abscess of the third patient proved positive for *Brucella suis*. The institution had its own dairy herd and "also kept swine", 9 of 32 hogs showed positive reaction to the agglutination test, and 7 more were classed as suspicious

THE MARCUS OUTBREAK

During the latter part of August and through Sept 8, 1941 the State Hygienic Laboratory of the Iowa State Department of Health reported a series of positive agglutination tests for brucellosis on blood serum specimens from a number of patients with residence in Marcus (population 1,200), Cherokee County, Iowa. Among the first 9 patients concerned, 1 had been in poor health for several years following nephrectomy for a kidney tumor, another had been in contact with farm animals preceding the onset of symptoms, and 4 of the remaining 7 were father and 3 children in the same family. The reporting of but 1 case of brucellosis in a small urban community would have reflected the usual sporadic incidence of this disease. The occurrence of multiple cases, and especially of 4 in the same family, made it certain that something extraordinary had happened, suggesting the possibility of a *Brucella suis* infection.

Investigation took place on September 10 in cooperation with the attending physician (co-author M. F. J.). Home visits were made to see the patients who had complained for several weeks of fever, headache, chills or chilliness, severe night sweats, loss of weight and strength, lassitude, pain and weakness in the legs and in some instances a rather severe cough. Only 1 of this group of patients had come in contact with farm animals, cows or hogs, during the months before illness. There was a common factor, however, in that all had been supplied with milk from a dairyman (the W. H. dairy) who delivered raw milk.

Control measures were instituted on September 10. Arrangements were made for four local dairymen, all of whom furnished raw milk, to have animals tested for evidence of infectious abortion. Pending the result of agglutination tests, all milk was to be pasteurized in a nearby pasteurizing plant, before delivery to the public. The owner of the W. H. dairy went out of business forthwith, to our knowledge no raw milk or cream from this dairy reached families of the community after September 10. Bang's disease reactors were not reported among other dairy herds which formed part of the milk supply of Marcus.

EXTENT AND EVIDENCES OF INFECTION

1 Occurrence of Additional Active and Latent Cases—Although the vehicle of infection, the suspected milk supply, was removed on September 10, new cases of brucellosis continued to appear throughout the remaining months of 1941 and into March of 1942. During the period from Aug. 12, 1941 to March 6, 1942 (including

findings of the school survey) the blood serum of 77 persons in the Marcus community, all of whom had used milk from the W. H. dairy, showed positive agglutination in diagnostic dilution against brucella antigen. The peak of the epidemic, based on the number of positive agglutination reports, was reached in October. Titers of 75 of the 77 individuals who showed positive agglutination in diagnostic dilutions were as follows: 1:40 (2), 1:80 (5), 1:160 (2), 1:320 (21), 1:640 (16), 1:1,280 (17), 1:2,560 (2).

2 Agglutination Survey—In order to obtain additional information regarding the extent of infection in the general population and to reveal latent or subclinical as well as clinical cases, agglutination tests were carried out on the serum of 237 persons in the parochial and public schools. The survey was made on October 21 in cooperation with parents and school officials. Twelve individuals (5.3 per cent) showed positive agglutination reactions for brucellosis in dilutions of from 1:80 to 1:2,560. Several members of the school group with positive agglutination findings had been sick or indisposed for several days during preceding weeks, others gave no history of illness and were apparently in good health. The simultaneous occurrence of subclinical along with clinical cases has been reported in previous brucellosis surveys conducted in Iowa.⁴

3 Skin Tests with Brucellergen—On November 10 intradermal tests with brucellergen made separately from *Brucella suis* and *Brucella abortus*, supplied through the courtesy of Dr. I. F. Huddleson, D. V. M., of Michigan State College, were carried out on 266 persons in the public and parochial schools. Positive reactions as observed after forty-eight hours consisted of a varying sized oval area of erythema, induration and edema, which diminished within seventy-two hours. Forty-eight (18.0 per cent) showed a positive test with brucellergen abortus and 61 (22.9 per cent) with brucellergen suis. Reactions were more pronounced with the porcine than with the bovine antigen. A severe reaction, characterized by local necrosis with sloughing of skin and subcutaneous tissue, was noted in 1 instance, that of a girl aged 17, whose serum was not examined for brucella agglutination but who was exposed to the contaminated milk supply.

4 Opsonocytaphagic Tests—Seventy-five persons in the school group furnished blood for the opsonocytaphagic test. Although 48 (64 per cent) of the reactions were interpreted as strong or very strong, there was no apparent relationship between such findings and exposure to the contaminated milk supply.

DISTRIBUTION OF CASES

One or more members of 51 families gave evidence of infection as revealed by positive agglutination tests or clinical illness. Multiple cases occurred in 15 homes. In the total group of 77, males numbered 44, females 33. The age group 1-9 included 29, of whom 11 were under 5 years of age. Eighteen were in the age group 10-19 and 20 in the group 20-39. The youngest patient was 7 months, the oldest 71 years of age.

INCUBATION PERIOD

The fact that positive agglutination reactions continued to occur for several months following removal of the contaminated milk supply on September 10 is

attributed to the insidious nature of brucellosis and to the long incubation period, which Hardy, Frant and Kroll⁵ found to vary from a week to four months

TREATMENT

Acute brucellosis is a febrile disease, requiring strict bed rest during the course of illness and for ten days to two weeks after the temperature has returned to normal. An ample bed rest period is probably the best assurance against extended illness as recurrence, complications and chronicity are less frequent when this regimen is followed.

In recent years the sulfonamide drugs have been used with varying success in the treatment of brucellosis. In the Marcus epidemic these drugs were used very sparingly, owing chiefly to the fact that all patients showed some degree of secondary anemia. In most instances the secondary anemia was a prominent finding, therefore sulfonamide therapy was withheld to avoid the possibility of adding insult to injury.

All the patients received brucellin, as developed by Huddleson and produced by the Iowa State Hygienic Laboratory. This preparation, a culture filtrate of brucella organisms, was given intramuscularly at intervals of three to five days dependent on symptoms. Brucellin is given subcutaneously in amount calculated to produce fever of 102 F or above within a short time following injection. In general, the initial injection was 0.1 cc and the dosage increased or diminished to achieve the desired febrile reaction. Maximum dosage was 1 cc. These treatments were administered until the patient received 1 cc of brucellin without febrile reaction. In most cases three repeated doses were given after the febrile reaction had ceased. The average number of injections was fifteen. After four treatments many of the patients had a temperature not exceeding 100 F in spite of increased strength of injections. One patient had a total of thirty treatments before the desired afebrile condition was achieved.

COURSE

The average duration of fever was six to eight weeks. One patient was severely ill and bedfast for twelve weeks. There were no fatalities—all patients were reported (May 21, 1942) as having made satisfactory recovery.

SOURCE OF INFECTION

1 *Blood Culture Findings*—In October and early November, blood cultures were obtained from 29 patients, specimens being incubated for a number of days, forwarded to the State Hygienic Laboratory and examined by one of us (I. H. B.). Of this number, *Brucella suis* was isolated from 13 or 45 per cent, had blood cultures been taken earlier in the course of the disease, a higher percentage of positives would have been expected. These findings confirmed the original conjecture that *Brucella suis* was the infecting agent. All the brucella strains isolated from this outbreak and identified as *Brucella suis* by the Huddleson method⁶ were verified by the author of the method.

2 *Findings on the Dairy Farm*—(a) *Dairy Cows*. Among 43 cows belonging to the W. H. Dairy, 4 reacting animals were encountered, 3 of which were definitely positive and a fourth one suspicious. *Brucella suis* was isolated from the milk of 2 of the reacting animals on direct culture of the gravity cream, using the Huddle-

son dye method and on blood and tryptose agar medium. On guinea pig inoculation *Brucella suis* was isolated from the cream of 3 of the reacting animals.

Lesions produced in guinea pigs inoculated with cream and with pure cultures isolated from the blood of ill patients at Marcus were mild in nature compared with lesions produced by other strains of *Brucella suis* previously isolated from similar sources. The laboratory and clinical findings suggest a *Brucella suis* strain of relatively low virulence. Whether virulence might have been reduced by residence in the cow's udder is a matter of speculation.

(b) *Sows on the Farm*. Inspection of the farm showed that hogs and dairy cows were allowed to mingle freely in the same lot. No history of frank abortion among sows was obtained, although the owner stated that about 20 young pigs, littered in the spring of 1941 were found dead after delivery, some living as long as a month. Blood tests on these animals, however, left no doubt as to their being infected. Twenty-four sows were tested of which 11 showed positive and 3 suggestive agglutination reactions for infectious abortion.

COMMENT

1 In recent years articles by Alice Evans⁷ and Simpson⁸ have emphasized the importance of the blood culture and of repeated agglutination tests in the diagnosis of brucellosis, in particular the chronic form of this disease.

2 In spite of the apparent efficacy of brucellin when administered early in the course of illness, there are individuals who react with extreme elevation of temperature and exhaustion following the initial dosages. Three such patients in the Marcus outbreak were given sulfathiazole with satisfactory response and recovery.

3 On farms regarded as the source of infection of *Brucella suis* as isolated from the blood of patients, we have found it not unusual to fail to secure a history of abortion among hogs. This observation is in agreement with the following quotation from McNutt⁹: "Although abortion is one of the symptoms of *Brucella suis* infection in swine, it does not occur in the larger portion of cases." Agglutination tests are essential to the discovery of infectious abortion among hogs.

4 One of the patients in the Marcus outbreak, an expectant mother with one healthy child, acquired brucellosis in moderately severe form, being confirmed by a positive agglutination test. She aborted twin embryos during the fourth or fifth month of gestation, there was no other discernible cause for the abortion.

5 Among multiple cases which occurred in different homes during this epidemic, it is of interest to note that all 6 members of one family and, in another home, 6 of a family of 12, suffered an attack of brucellosis.

SUMMARY AND CONCLUSIONS

An epidemic of brucellosis included 77 persons who showed positive clinical or agglutination findings caused by the porcine strain of *Brucella* (*Brucella suis*) in a raw milk supply.

1 Isolation of *Brucella* from a blood culture stands first as a diagnostic aid in confirming the clinical diagnosis of brucellosis. Such isolation moreover, when

reported by Beattie and Rice² *Brucella suis* was isolated from the milk of a reacting dairy cow and from the blood of 6 patients

In 1934-1935 a brucellosis outbreak occurred in an institution of elderly persons in Connecticut. The report by Horning³ states that 14 cases developed in a group of 305 inmates and 81 employees. Among 3 fatal cases, blood cultures of 2 and culture of an abscess of the third patient proved positive for *Brucella suis*. The institution had its own dairy herd and "also kept swine", 9 of 32 hogs showed positive reaction to the agglutination test, and 7 more were classed as suspicious.

THE MARCUS OUTBREAK

During the latter part of August and through Sept 8, 1941 the State Hygienic Laboratory of the Iowa State Department of Health reported a series of positive agglutination tests for brucellosis on blood serum specimens from a number of patients with residence in Marcus (population 1,200), Cherokee County, Iowa. Among the first 9 patients concerned, 1 had been in poor health for several years following nephrectomy for a kidney tumor, another had been in contact with farm animals preceding the onset of symptoms, and 4 of the remaining 7 were father and 3 children in the same family. The reporting of but 1 case of brucellosis in a small urban community would have reflected the usual sporadic incidence of this disease. The occurrence of multiple cases, and especially of 4 in the same family, made it certain that something extraordinary had happened, suggesting the possibility of a *Brucella suis* infection.

Investigation took place on September 10 in cooperation with the attending physician (co-author M. F. J.). Home visits were made to see the patients who had complained for several weeks of fever, headache, chills or chilliness, severe night sweats, loss of weight and strength, lassitude, pain and weakness in the legs and in some instances a rather severe cough. Only 1 of this group of patients had come in contact with farm animals, cows or hogs, during the months before illness. There was a common factor, however, in that all had been supplied with milk from a dairyman (the W. H. dairy) who delivered raw milk.

Control measures were instituted on September 10. Arrangements were made for four local dairymen, all of whom furnished raw milk, to have animals tested for evidence of infectious abortion. Pending the result of agglutination tests, all milk was to be pasteurized in a nearby pasteurizing plant, before delivery to the public. The owner of the W. H. dairy went out of business forthwith, to our knowledge no raw milk or cream from this dairy reached families of the community after September 10. Bang's disease reactors were not reported among other dairy herds which formed part of the milk supply of Marcus.

EXTENT AND EVIDENCES OF INFECTION

1 Occurrence of Additional Active and Latent Cases—Although the vehicle of infection, the suspected milk supply, was removed on September 10, new cases of brucellosis continued to appear throughout the remaining months of 1941 and into March of 1942. During the period from Aug. 12, 1941 to March 6, 1942 (including

findings of the school survey) the blood serum of 77 persons in the Marcus community, all of whom had used milk from the W. H. dairy, showed positive agglutination in diagnostic dilution against brucella antigen. The peak of the epidemic, based on the number of positive agglutination reports, was reached in October. Titers of 75 of the 77 individuals who showed positive agglutination in diagnostic dilutions were as follows: 1/40 (2), 1/80 (5), 1/160 (2), 1/320 (21), 1/640 (16), 1/1,280 (17), 1/2,560 (2).

2 Agglutination Survey—In order to obtain additional information regarding the extent of infection in the general population and to reveal latent or subclinical as well as clinical cases, agglutination tests were carried out on the serum of 237 persons in the parochial and public schools. The survey was made on October 21 in cooperation with parents and school officials. Twelve individuals (5.3 per cent) showed positive agglutination reactions for brucellosis in dilutions of from 1/80 to 1/2,560. Several members of the school group with positive agglutination findings had been sick or indisposed for several days during preceding weeks, others gave no history of illness and were apparently in good health. The simultaneous occurrence of subclinical along with clinical cases has been reported in previous brucellosis surveys conducted in Iowa.⁴

3 Skin Tests with Brucellergen—On November 10 intradermal tests with brucellergen made separately from *Brucella suis* and *Brucella abortus*, supplied through the courtesy of Dr. I. F. Huddleson, D. V. M., of Michigan State College, were carried out on 266 persons in the public and parochial schools. Positive reactions as observed after forty-eight hours consisted of a varying sized oval area of erythema, induration and edema, which diminished within seventy-two hours. Forty-eight (18.0 per cent) showed a positive test with brucellergen *abortus* and 61 (22.9 per cent) with brucellergen *suis*. Reactions were more pronounced with the porcine than with the bovine antigen. A severe reaction, characterized by local necrosis with sloughing of skin and subcutaneous tissue, was noted in 1 instance, that of a girl aged 17, whose serum was not examined for brucella agglutination but who was exposed to the contaminated milk supply.

4 Opsonocytophagic Tests—Seventy-five persons in the school group furnished blood for the opsonocytophagic test. Although 48 (64 per cent) of the reactions were interpreted as strong or very strong, there was no apparent relationship between such findings and exposure to the contaminated milk supply.

DISTRIBUTION OF CASES

One or more members of 51 families gave evidence of infection as revealed by positive agglutination tests or clinical illness. Multiple cases occurred in 15 homes. In the total group of 77, males numbered 44, females 33. The age group 1-9 included 29, of whom 11 were under 5 years of age. Eighteen were in the age group 10-19 and 20 in the group 20-39. The youngest patient was 7 months, the oldest 71 years of age.

INCUBATION PERIOD

The fact that positive agglutination reactions continued to occur for several months following removal of the contaminated milk supply on September 10 is

attributed to the insidious nature of brucellosis and to the long incubation period, which Hardy, Frant and Kroll⁵ found to vary from a week to four months

TREATMENT

Acute brucellosis is a febrile disease, requiring strict bed rest during the course of illness and for ten days to two weeks after the temperature has returned to normal. An ample bed rest period is probably the best assurance against extended illness, as recurrence, complications and chronicity are less frequent when this regimen is followed.

In recent years the sulfonamide drugs have been used with varying success in the treatment of brucellosis. In the Marcus epidemic these drugs were used very sparingly, owing chiefly to the fact that all patients showed some degree of secondary anemia. In most instances the secondary anemia was a prominent finding, therefore sulfonamide therapy was withheld to avoid the possibility of adding insult to injury.

All the patients received brucellin, as developed by Huddleson and produced by the Iowa State Hygienic Laboratory. This preparation, a culture filtrate of brucella organisms, was given intramuscularly at intervals of three to five days dependent on symptoms. Brucellin is given subcutaneously in amount calculated to produce fever of 102 F or above within a short time following injection. In general, the initial injection was 0.1 cc and the dosage increased or diminished to achieve the desired febrile reaction. Maximum dosage was 1 cc. These treatments were administered until the patient received 1 cc of brucellin without febrile reaction. In most cases three repeated doses were given after the febrile reaction had ceased. The average number of injections was fifteen. After four treatments many of the patients had a temperature not exceeding 100 F in spite of increased strength of injections. One patient had a total of thirty treatments before the desired afebrile condition was achieved.

COURSE

The average duration of fever was six to eight weeks. One patient was severely ill and bedfast for twelve weeks. There were no fatalities—all patients were reported (May 21, 1942) as having made satisfactory recovery.

SOURCE OF INFECTION

1 *Blood Culture Findings*—In October and early November, blood cultures were obtained from 29 patients, specimens being incubated for a number of days, forwarded to the State Hygienic Laboratory and examined by one of us (I. H. B.). Of this number, *Brucella suis* was isolated from 13 or 45 per cent, had blood cultures been taken earlier in the course of the disease, a higher percentage of positives would have been expected. These findings confirmed the original conjecture that *Brucella suis* was the infecting agent. All the brucella strains isolated from this outbreak and identified as *Brucella suis* by the Huddleson method⁶ were verified by the author of the method.

2 *Findings on the Dairy Farm*—(a) *Dairy Cows*. Among 43 cows belonging to the W. H. Dairy, 4 reacting animals were encountered, 3 of which were definitely positive and a fourth one suspicious. *Brucella suis* was isolated from the milk of 2 of the reacting animals on direct culture of the gravity cream, using the Huddle-

son dye method and on blood and tryptose agar medium. On guinea pig inoculation *Brucella suis* was isolated from the cream of 3 of the reacting animals.

Lesions produced in guinea pigs inoculated with cream and with pure cultures isolated from the blood of ill patients at Marcus were mild in nature compared with lesions produced by other strains of *Brucella suis* previously isolated from similar sources. The laboratory and clinical findings suggest a *Brucella suis* strain of relatively low virulence. Whether virulence might have been reduced by residence in the cow's udder is a matter of speculation.

(b) *Sows on the Farm*. Inspection of the farm showed that hogs and dairy cows were allowed to mingle freely in the same lot. No history of frank abortion among sows was obtained, although the owner stated that about 20 young pigs, littered in the spring of 1941, were found dead after delivery, some living as long as a month. Blood tests on these animals, however, left no doubt as to their being infected. Twenty-four sows were tested of which 11 showed positive and 3 suggestive agglutination reactions for infectious abortion.

COMMENT

1 In recent years articles by Alice Evans⁷ and Simpson⁸ have emphasized the importance of the blood culture and of repeated agglutination tests in the diagnosis of brucellosis, in particular the chronic form of this disease.

2 In spite of the apparent efficacy of brucellin when administered early in the course of illness, there are individuals who react with extreme elevation of temperature and exhaustion following the initial dosages. Three such patients in the Marcus outbreak were given sulfathiazole with satisfactory response and recovery.

3 On farms regarded as the source of infection of *Brucella suis* as isolated from the blood of patients, we have found it not unusual to fail to secure a history of abortion among hogs. This observation is in agreement with the following quotation from McNutt⁹: "Although abortion is one of the symptoms of *Brucella suis* infection in swine, it does not occur in the larger portion of cases." Agglutination tests are essential to the discovery of infectious abortion among hogs.

4 One of the patients in the Marcus outbreak, an expectant mother with one healthy child, acquired brucellosis in moderately severe form, being confirmed by a positive agglutination test. She aborted twin embryos during the fourth or fifth month of gestation, there was no other discernible cause for the abortion.

5 Among multiple cases which occurred in different homes during this epidemic, it is of interest to note that all 6 members of one family and, in another home, 6 of a family of 12, suffered an attack of brucellosis.

SUMMARY AND CONCLUSIONS

An epidemic of brucellosis included 77 persons who showed positive clinical or agglutination findings caused by the porcine strain of *Brucella* (*Brucella suis*) in a raw milk supply.

1 Isolation of *Brucella* from a blood culture stands first as a diagnostic aid in confirming the clinical diagnosis of brucellosis. Such isolation, moreover, when

reported by Beattie and Rice² *Brucella suis* was isolated from the milk of a reacting dairy cow and from the blood of 6 patients

In 1934-1935 a brucellosis outbreak occurred in an institution of elderly persons in Connecticut. The report by Horning³ states that 14 cases developed in a group of 305 inmates and 81 employees. Among 3 fatal cases, blood cultures of 2 and culture of an abscess of the third patient proved positive for *Brucella suis*. The institution had its own dairy herd and "also kept swine", 9 of 32 hogs showed positive reaction to the agglutination test, and 7 more were classed as suspicious

THE MARCUS OUTBREAK

During the latter part of August and through Sept 8, 1941 the State Hygienic Laboratory of the Iowa State Department of Health reported a series of positive agglutination tests for brucellosis on blood serum specimens from a number of patients with residence in Marcus (population 1,200), Cherokee County, Iowa. Among the first 9 patients concerned, 1 had been in poor health for several years following nephrectomy for a kidney tumor, another had been in contact with farm animals preceding the onset of symptoms, and 4 of the remaining 7 were father and 3 children in the same family. The reporting of but 1 case of brucellosis in a small urban community would have reflected the usual sporadic incidence of this disease. The occurrence of multiple cases, and especially of 4 in the same family, made it certain that something extraordinary had happened, suggesting the possibility of a *Brucella suis* infection.

Investigation took place on September 10 in cooperation with the attending physician (co-author M. F. J.). Home visits were made to see the patients who had complained for several weeks of fever, headache, chills or chilliness, severe night sweats, loss of weight and strength, lassitude, pain and weakness in the legs and in some instances a rather severe cough. Only 1 of this group of patients had come in contact with farm animals, cows or hogs, during the months before illness. There was a common factor, however, in that all had been supplied with milk from a dairyman (the W. H. dairy) who delivered raw milk.

Control measures were instituted on September 10. Arrangements were made for four local dairymen, all of whom furnished raw milk, to have animals tested for evidence of infectious abortion. Pending the result of agglutination tests, all milk was to be pasteurized in a nearby pasteurizing plant, before delivery to the public. The owner of the W. H. dairy went out of business forthwith, to our knowledge no raw milk or cream from this dairy reached families of the community after September 10. Bang's disease reactors were not reported among other dairy herds which formed part of the milk supply of Marcus.

EXTENT AND EVIDENCES OF INFECTION

1 Occurrence of Additional Active and Latent Cases—Although the vehicle of infection, the suspected milk supply, was removed on September 10, new cases of brucellosis continued to appear throughout the remaining months of 1941 and into March of 1942. During the period from Aug. 12, 1941 to March 6, 1942 (including

findings of the school survey) the blood serum of 77 persons in the Marcus community, all of whom had used milk from the W. H. dairy, showed positive agglutination in diagnostic dilution against brucella antigen. The peak of the epidemic, based on the number of positive agglutination reports, was reached in October. Titers of 75 of the 77 individuals who showed positive agglutination in diagnostic dilutions were as follows: 1:40 (2), 1:80 (5), 1:160 (2), 1:320 (21), 1:640 (16), 1:1,280 (17), 1:2,560 (2).

2 Agglutination Survey—In order to obtain additional information regarding the extent of infection in the general population and to reveal latent or subclinical as well as clinical cases, agglutination tests were carried out on the serum of 237 persons in the parochial and public schools. The survey was made on October 21 in cooperation with parents and school officials. Twelve individuals (5.3 per cent) showed positive agglutination reactions for brucellosis in dilutions of from 1:80 to 1:2,560. Several members of the school group with positive agglutination findings had been sick or indisposed for several days during preceding weeks, others gave no history of illness and were apparently in good health. The simultaneous occurrence of subclinical along with clinical cases has been reported in previous brucellosis surveys conducted in Iowa.⁴

3 Skin Tests with Brucellergen—On November 10 intradermal tests with brucellergen made separately from *Brucella suis* and *Brucella abortus*, supplied through the courtesy of Dr. I. F. Huddleson, D. V. M., of Michigan State College, were carried out on 266 persons in the public and parochial schools. Positive reactions as observed after forty-eight hours consisted of a varying sized oval area of erythema, induration and edema, which diminished within seventy-two hours. Forty-eight (18.0 per cent) showed a positive test with brucellergen abortus and 61 (22.9 per cent) with brucellergen suis. Reactions were more pronounced with the porcine than with the bovine antigen. A severe reaction, characterized by local necrosis with sloughing of skin and subcutaneous tissue, was noted in 1 instance, that of a girl aged 17, whose serum was not examined for brucella agglutination but who was exposed to the contaminated milk supply.

4 Opsonocytophagic Tests—Seventy-five persons in the school group furnished blood for the opsonocytophagic test. Although 48 (64 per cent) of the reactions were interpreted as strong or very strong, there was no apparent relationship between such findings and exposure to the contaminated milk supply.

DISTRIBUTION OF CASES

One or more members of 51 families gave evidence of infection as revealed by positive agglutination tests or clinical illness. Multiple cases occurred in 15 homes. In the total group of 77, males numbered 44, females 33. The age group 1-9 included 29, of whom 11 were under 5 years of age. Eighteen were in the age group 10-19 and 20 in the group 20-39. The youngest patient was 7 months, the oldest 71 years of age.

INCUBATION PERIOD

The fact that positive agglutination reactions continued to occur for several months following removal of the contaminated milk supply on September 10 is

attributed to the insidious nature of brucellosis and to the long incubation period, which Hardy, Frant and Kroll⁵ found to vary from a week to four months

TREATMENT

Acute brucellosis is a febrile disease, requiring strict bed rest during the course of illness and for ten days to two weeks after the temperature has returned to normal. An ample bed rest period is probably the best assurance against extended illness, as recurrence, complications and chronicity are less frequent when this regimen is followed.

In recent years the sulfonamide drugs have been used with varying success in the treatment of brucellosis. In the Marcus epidemic these drugs were used very sparingly, owing chiefly to the fact that all patients showed some degree of secondary anemia. In most instances the secondary anemia was a prominent finding, therefore sulfonamide therapy was withheld to avoid the possibility of adding insult to injury.

All the patients received brucellin, as developed by Huddleson and produced by the Iowa State Hygienic Laboratory. This preparation, a culture filtrate of brucella organisms, was given intramuscularly at intervals of three to five days dependent on symptoms. Brucellin is given subcutaneously in amount calculated to produce fever of 102 F or above within a short time following injection. In general, the initial injection was 0.1 cc and the dosage increased or diminished to achieve the desired febrile reaction. Maximum dosage was 1 cc. These treatments were administered until the patient received 1 cc of brucellin without febrile reaction. In most cases three repeated doses were given after the febrile reaction had ceased. The average number of injections was fifteen. After four treatments many of the patients had a temperature not exceeding 100 F in spite of increased strength of injections. One patient had a total of thirty treatments before the desired afebrile condition was achieved.

COURSE

The average duration of fever was six to eight weeks. One patient was severely ill and bedfast for twelve weeks. There were no fatalities—all patients were reported (May 21, 1942) as having made satisfactory recovery.

SOURCE OF INFECTION

1 *Blood Culture Findings*—In October and early November, blood cultures were obtained from 29 patients, specimens being incubated for a number of days, forwarded to the State Hygienic Laboratory and examined by one of us (I. H. B.). Of this number, *Brucella suis* was isolated from 13 or 45 per cent, had blood cultures been taken earlier in the course of the disease, a higher percentage of positives would have been expected. These findings confirmed the original conjecture that *Brucella suis* was the infecting agent. All the brucella strains isolated from this outbreak and identified as *Brucella suis* by the Huddleson method⁶ were verified by the author of the method.

2 *Findings on the Dairy Farm*—(a) *Dairy Cows*. Among 43 cows belonging to the W. H. Dairy, 4 reacting animals were encountered, 3 of which were definitely positive and a fourth one suspicious. *Brucella suis* was isolated from the milk of 2 of the reacting animals on direct culture of the gravity cream, using the Huddle-

son dye method and on blood and tryptose agar medium. On guinea pig inoculation *Brucella suis* was isolated from the cream of 3 of the reacting animals.

Lesions produced in guinea pigs inoculated with cream and with pure cultures isolated from the blood of ill patients at Marcus were mild in nature compared with lesions produced by other strains of *Brucella suis* previously isolated from similar sources. The laboratory and clinical findings suggest a *Brucella suis* strain of relatively low virulence. Whether virulence might have been reduced by residence in the cow's udder is a matter of speculation.

(b) *Sows on the Farm*. Inspection of the farm showed that hogs and dairy cows were allowed to mingle freely in the same lot. No history of frank abortion among sows was obtained, although the owner stated that about 20 young pigs, littered in the spring of 1941, were found dead after delivery, some living as long as a month. Blood tests on these animals, however, left no doubt as to their being infected. Twenty-four sows were tested of which 11 showed positive and 3 suggestive agglutination reactions for infectious abortion.

COMMENT

1 In recent years articles by Alice Evans⁷ and Simpson⁸ have emphasized the importance of the blood culture and of repeated agglutination tests in the diagnosis of brucellosis, in particular the chronic form of this disease.

2 In spite of the apparent efficacy of brucellin when administered early in the course of illness, there are individuals who react with extreme elevation of temperature and exhaustion following the initial dosages. Three such patients in the Marcus outbreak were given sulfathiazole with satisfactory response and recovery.

3 On farms regarded as the source of infection of *Brucella suis* as isolated from the blood of patients, we have found it not unusual to fail to secure a history of abortion among hogs. This observation is in agreement with the following quotation from McNutt⁹: "Although abortion is one of the symptoms of *Brucella suis* infection in swine, it does not occur in the larger portion of cases." Agglutination tests are essential to the discovery of infectious abortion among hogs.

4 One of the patients in the Marcus outbreak, an expectant mother with one healthy child, acquired brucellosis in moderately severe form, being confirmed by a positive agglutination test. She aborted twin embryos during the fourth or fifth month of gestation, there was no other discernible cause for the abortion.

5 Among multiple cases which occurred in different homes during this epidemic, it is of interest to note that all 6 members of one family and, in another home, 6 of a family of 12, suffered an attack of brucellosis.

SUMMARY AND CONCLUSIONS

An epidemic of brucellosis included 77 persons who showed positive clinical or agglutination findings caused by the porcine strain of *Brucella* (*Brucella suis*) in a raw milk supply.

1 Isolation of *Brucella* from a blood culture stands first as a diagnostic aid in confirming the clinical diagnosis of brucellosis. Such isolation, moreover, when

supplemented by the Huddleson dye method, reveals the species of organism and is of great value in establishing the animal source of infection

2 The agglutination test, repeated when negative, is second as a diagnostic aid to isolation of *Brucella* from the blood stream

3 A positive intradermal test with brucellergen indicates recent or past exposure to brucella infection but "does not mean that the symptoms from which the patient is suffering at the time are necessarily due to brucellosis" (Simpson⁸) The skin test is much less reliable than the agglutination test in diagnosis

4 Careful pasteurization of all dairy products is an essential safeguard against milk borne brucellosis

5 Hogs should not be permitted to run on the same lot with dairy cows

6 Prevention of the occurrence of brucellosis in human beings requires a continuing program and effective measures for the eradication of infectious abortion among farm animals

THE PREVENTION OF LIVER DAMAGE

AND THE FACILITATION OF REPAIR IN THE LIVER BY DIET

I S RAVDIN, MD
ELIZABETH THOROGOOD, AB
CECILIA RIEGEL, PH D
ROZANNE PETERS, AB
AND
J E RHOADS, MD
PHILADELPHIA

Although it is generally believed that attempts to improve the resistance of the liver to injury from hepatotoxic agents is a contribution of the present century, elaborate studies in this field were undertaken during the nineteenth century¹ It was, however, the experiments of Opie and Alford² which led clinicians, at least in this country, to believe that a diet high in carbohydrate offered direct protection of the liver from the necrotizing effects of chloroform Their work received confirmation in the later experiments of Davis, Hall and Whipple³ and Graham⁴

The unfortunate interpretation which clinicians placed on the results of these investigations led them to conclude that a high concentration of liver glycogen would in itself protect the liver from injury from a wide variety of agents, that the detoxifying power of the liver was proportional to its glycogen content and finally that hepatic regeneration would proceed more rapidly on a high carbohydrate diet than on any other

In the early 1920's less and less emphasis came to be placed on the oral intake of foodstuffs in preparing the bad risk liver patient for operation and greater emphasis on the administration of intravenously injected dextrose The rationale which led to this extension

of therapy has been recently summarized by Soskin and Hyman⁵ Authors have repeatedly referred to the fact that larger amounts of dextrose could be deposited in the liver when the carbohydrate was administered intravenously than when equivalent amounts of carbohydrate were given orally (Banks and Sears⁶), although it rarely has been considered that larger amounts of foodstuffs can be given by the latter route than by the former

It can be accepted as a fact that storage in important viscera will depend on a food intake sufficient to meet energy requirements on the one hand and to provide for food storage on the other To believe that storage over any period of hours can take place when food intake falls below the needs for energy requirements is to disregard the fundamental laws governing metabolism To perpetuate the statement that "cellular repair of the liver is best facilitated by a carbohydrate diet"⁶ violates the fundamental knowledge available to us on cellular repair, for such repair in the main is dependent on protein components available to the regenerating tissue, and on a strictly carbohydrate diet repair would have to depend entirely on the breakdown of endogenous protein Sanders and Garrison⁷ have shown that the products of endogenous protein breakdown do not take the place of the protein in an adequate diet during wound repair

In 1924 Moise and Smith⁸ called attention to the fact that the diets used by the earlier investigators were neither pure (in the sense of consisting of single foodstuffs) nor adequate in amount for young growing dogs, which were the animals used by the investigators In spite of this, many of us continued to place complete confidence in the carbohydrate diet as a means of protecting the liver from the assault of anesthesia and operation (Ravdin⁹)

It was better to provide in part for the energy requirements of the patient than to bring the patient to operation following a period of starvation Where intravenous dextrose therapy reinforced oral feeding, the program accomplished a good deal and the morbidity and mortality of operations on many of the patients with serious liver dysfunction fell considerably

In 1939 Goldschmidt, Vars and Ravdin¹⁰ reported that maximum protection could not be afforded the liver against chloroform necrosis unless the diet was adequate in composition and amount, and administered for a sufficient time prior to exposure to the hepatotoxic agent They concluded that a liver high in lipid content and high in available protein was maximally protected against injury

Carbohydrate protected the liver from injury if, during the deposition of glycogen in the liver, fat was displaced, according to the hypothesis of Rosenfeld,¹ and if the ingested carbohydrate spared the body stores of protein Protein, on the other hand, was found to be a much more active lipotropic agent than carbohydrate (Johnson, Ravdin, Vars and Zintel¹¹) and, in addition, certain components of the protein molecule directly

usually with stones in the common duct and many of them had been or were jaundiced at the time of admission to the hospital. Most of them were, in addition, moderately or decidedly obese, a factor which we have come to realize must be considered in deciding whether the patient should or should not be placed on a diet for some days prior to operation.

It was not always possible to get the patient to eat as much as we thought was necessary, and in such instances we have at times resorted to tube feeding, a method which is not used as frequently as it should be. In addition to the diet the patients received 100 mg. of thiamine hydrochloride and one of the potent bile salt preparations. Such accessory therapy is, we believe, useful.

TABLE 2—The Relation of Obesity to Hepatic Fatty Acid

Build	No. of Patients	Fatty Acid Gm. per 100 Cc
Average	31	3.9
Under normal	7	3.2
Obesity +	12	4.6
Obesity ++	21	6.1
Obesity +++	5	10.3±

A few years ago we found that approximately 29 per cent of patients with long standing gallstone disease had abnormally high amounts of lipid present in the liver. We have now studied the composition of the liver in 127 patients operated on for biliary tract disease. The operations were all done under local or spinal anesthesia. Some of the patients were not on a special diet prior to operation, while others were on a diet which we considered adequate in composition and amount for from five days to one month prior to operation.

The diet consisted of approximately 74 per cent of carbohydrate, 20 per cent of protein and not more than 6 per cent of fat. The carbohydrate was in large part obtained from the banana, for this foodstuff was found to be well tolerated by the patients. The protein in large part consisted of casein in the form of cottage cheese, skimmed milk and Casec. (A sample diet is given in table 1.) The diet must be varied in order to encourage the patient to eat a sufficient amount of food.

Only those patients were placed on a diet who gave evidence of long standing disease or serious interference with biliary function or who were jaundiced at the time of admission to the hospital. The patients operated on shortly after admission to the hospital did not appear to be ill or gave little or no evidence of serious hepatic injury.

This paper is based on the data obtained from 127 patients. Of these 37 were maintained for five days or more prior to operation on a diet adequate in composition and in caloric intake. In any consideration of diet it is important to select a diet which is adequate in the various constituents and which, at the same time, is sufficiently variable so that it will not become monotonous. It is important not only that the patients be offered a satisfactory diet but that they eat it. It cannot be too strongly pointed out that a high caloric intake is just as important as the composition of the food.

The patients we have had on a diet were all bad risk patients who had long standing biliary tract disease.

THE RELATION OF OBESITY TO HEPATIC FATTY ACID

An accurate record was kept of the build of 76 patients not on the diet. The data are given in table 2. It can be seen that increasing obesity is, as a rule, associated with an increasing concentration of hepatic lipid. It is interesting to note that the supposed inverse relationship between hepatic lipid and glycogen concentrations was not always present in these patients. Some of the highest hepatic glycogen concentrations were found in patients whose hepatic fatty acid concentrations were above 12 per cent. Conversely, some of the very low hepatic glycogen concentrations, 1 per cent or below, were found in patients with a normal fatty acid concentration. The reciprocal relationship between glycogen and fat described by Rosenfeld,¹ as a rule, was not found in these patients. No reliance, therefore, must be placed on the concentration of liver glycogen as an indicator of the lipid concentration.

THE RELATION OF HISTOLOGIC DIAGNOSIS TO HEPATIC FATTY ACID

We have come to know that the amount of fatty acids found by chemical analysis does not always closely parallel the amount found by histologic staining meth-

TABLE 3—Microscopic Diagnosis of Fatty Infiltration

	No. of Patients	Glycogen	Fatty Acid Gm. per 100 Cc
Mild fatty infiltration	18	2.8	4.6
Moderate fatty infiltration	31	3.5	5.1
Marked fatty infiltration	11	3.5	10.9

TABLE 4—Composition of the Liver

	No. of Patients	Mean Glycogen Gm. per 100 Cc	Mean Fatty Acid Gm. per 100 Cc
Patients not on diet	90	3.0	5.1
Patients with microscopically normal livers	16	2.8	4.1
Patients with severe disease not receiving the diet	10	3.2	14.2
Patients with severe disease receiving the diet	37	2.3	4.2

ods. It can be seen, however, from table 3 that the presence of large amounts of lipid as determined by staining methods does closely follow the chemical determinations.

THE EFFECT OF DIET ON HEPATIC LIPID

In table 4 are given data which we believe demonstrate that an adequate diet, administered in sufficient amounts and for a long enough period, can condition

12 Messinger W. J. and Hawkins W. B. *Am. J. M. Sc.* 199 216 (Feb.) 1940.

14 Smith M. I., Lillie R. D. and Stohlman E. F. *Pub. Health Rep.* 56: 24 (Jan. 3) 1941.

a liver to minimal injury from a wide variety of hepatotoxic agents. The 37 patients who were on the diet had advanced biliary tract disease. The great majority of such patients without a period of preparation prior to operation run the risk of a variable degree of further degeneration or even necrosis subsequent to anesthetization and the trauma of operation.

The highest fatty acid concentration in the 37 patients on the diet was 7.4 Gm per hundred cubic centimeters while the mean fatty acid concentration was 4.2 Gm per hundred cubic centimeters. On the other hand, a group of 10 patients who were not so well prepared but who had comparable degrees of hepatic injury as determined by microscopic examinations had a mean fatty acid concentration of 14.2 Gm per hundred cubic centimeters.

These data should be compared with those obtained from patients operated on for gallbladder disease but whose livers were reported as histologically normal. In these the hepatic fatty acid and glycogen concentrations were approximately the same as those which were obtained from the livers of patients with advanced hepatic histologic change but who had been on a diet for five or more days prior to operation.

The data demonstrate that one can by diet bring about a change in the liver so that the concentrations of glycogen and fatty acids are practically identical with those found in histologically normal livers. It is interesting to note that the mean concentration of glycogen in the last two groups was the same, while the mean fatty acid concentration varied by more than 300 per cent.

THE REGENERATION OF THE LIVER

It is generally agreed that hepatic regeneration takes place rapidly when circumstances favorable to regeneration are offered. For regeneration to proceed at a maximum rate it is necessary that the organism be offered foodstuffs which supply in maximum amount those components which must be utilized for cellular repair. Schultz and Vars¹⁵ have found in the rat that repair is associated with a change in the ratio between the total liver protein and the nucleoprotein, the latter fraction increasing in amount during the period of repair. Such repair can be facilitated greatly if foodstuffs containing nuclear material are present in the diet during this period. Regardless of any other factors which may be involved, it has been found by them that the food best suited for facilitating this repair is liver itself.

During the past year we have placed our convalescing bad risk biliary tract patients on a diet which while similar in caloric intake and distribution to that used prior to operation, contains a generous share of the protein as liver. While it is difficult to evaluate such a procedure in man without further chemical and histologic data, we have been impressed with the smoothness of the convalescence of these patients and with the rapidity with which abnormalities of function which existed prior to operation have returned to normal thereafter. While casein is an active lipotropic agent and provides in maximal amounts those components of protein which provide protection from hepatotoxic agents, liver protein is more useful during periods when repair is desirable. Thus specificity in the protein provided during different phases of care receives additional significance.

SUMMARY

1 The ingestion of carbohydrate alone does not afford maximal protection to the liver against a variety of hepatotoxic agents.

2 Glycogen cannot be accumulated in the liver over a considerable number of hours unless the individual is receiving a caloric intake in excess of his basal requirements.

3 Dextrose injected intravenously frequently fails to raise the liver glycogen because the total caloric requirement of the patient is not being provided.

4 Chemical analyses of liver biopsies showed striking correlation between the obesity of the patient and the lipid content of the liver.

5 Chemical analyses of the liver tissue of 37 patients obtained at operation indicates that a dietary regimen based on animal experimental work previously reported is effective in restoring the liver glycogen and liver lipid concentration of patients with severe microscopic damage to the values found in patients with simple cholecystic disease.

6 The average lipid content of severely damaged livers from 10 patients who were not prepared by diet was 14.2 per cent. The average lipid content of 37 patients who were prepared five days or longer with diet was 4.2 per cent. The glycogen content in the latter group was 3.3 per cent as compared with 2.8 per cent in a control group composed of specimens from 16 patients not receiving diet but with microscopically normal livers.

The diet employed consisted of at least 20 per cent protein, not over 6 per cent fat and 74 per cent carbohydrate. An adequate caloric intake is most important and was insisted on.

Before operation most of the protein content was in the form of casein. Following operation calf's liver is preferred on the basis of the experiments of Vars and Schultz,¹⁵ which indicate that it facilitates the regeneration of liver tissue most effectively.

ABSTRACT OF DISCUSSION

DR. WALTER E. LEE, Philadelphia: This work, if confirmed, will mean the necessity for abandoning our faith in carbohydrates as the only agent to prepare patients with liver damage for surgery, the appreciation that, in addition, we must use protein, and that the ideal protein is liver tissue itself. The early work of Opie, Alfred, Davis and Hall and Whipple, which dates to 1914, and their conclusions that a high concentration of liver glycogen amply provided the necessary protection from a wide variety of agents, such as trauma, anesthesia and other toxic substances, was generally accepted, even by Ravdin, as late as 1929. In 1939 he first called attention to the fact that it was only when the liver was high in lipid content and available protein that its maximum protection against injury existed, and as a corollary that protein was far more active as a hepatotropic agent than the carbohydrates. His suggestions as well as his experiments on animals and human beings are that this ideal diet which Drs. Ravdin and Rhoads have outlined is all right but it must be so palatable that the patients can eat it. Ravdin has found that, if it is not palatable and the patient refuses to take it, its need is so definite that it should be given by tube. As a result of their continued animal experiments and clinical work he is convinced that an adequate diet, as outlined in this paper, in sufficient amounts and given for a long enough time, will condition the liver against a large number of hepatotoxic agents and that when the liver is not so conditioned preoperatively there always exists the risk of liver damage in the form of degeneration and necrosis, as follow the routine anesthetic agents and operative trauma. Ravdin claims that patients when prepared by protein in addition to carbohydrate

¹⁵ Vars, H. M. and Schultz, Julius. Personal communication to the authors.

will have but one third of the fatty acid concentration present, compared to those who are not so prepared, in other words, one third of those not prepared will have two thirds more fatty acid concentration. By taking tissue from the liver at the time of operation of patients who have been prepared with protein, they have found that it is quite possible to place the liver in a normal condition and that when they are not so prepared the figures already stated have been more or less constant. It would seem that he has demonstrated the fallacy of our depending entirely on the carbohydrate diet for the preoperative preparation of patients with damaged livers and he has made a constructive suggestion that by adding adequate protein to the carbohydrate diet it is possible preoperatively to place the liver of the patient in almost a normal condition.

TREATMENT OF BRONCHIAL ASTHMA

A SURVEY OF THE VALUE OF TREATMENT IN
FOUR HUNDRED AND FIFTY-NINE CASES
DURING TWENTY YEARS

LEON UNGER, M.D.
AND
A. ALVIN WOLF, M.D.
CHICAGO

The practice of allergy has developed into a major medical science within the past twenty years. It now seems advisable to analyze the results obtained in the treatment of the most important allergic condition, bronchial asthma.

This survey is divided into two parts. The first deals with the condition at this time in 207 cases previously reported¹. The second concerns an additional 252 cases. No case was included unless the period of at least one year had elapsed since treatment was started, and this period of observation ranged up to twenty years. Cases from private practice were utilized in both studies because the cooperation of this group is greatly superior to and the information obtained much more reliable than that which can be secured in the clinic.

METHODS OF INVESTIGATION

Every effort was made to obtain correct information. With patients no longer under treatment, the data were usually secured by a questionnaire (fig. 1), with a return self addressed, stamped envelop, this brought in a fairly large number of answers, but in some cases a follow-up letter was more successful. Personal telephone calls were sometimes necessary, and, in a number of instances, the physician who had referred the patient was able to comment on the present status. A summarizing card (fig. 2) was made out for each patient and those still under observation or treatment had the card filled out directly from the history chart.

DIAGNOSIS OF BRONCHIAL ASTHMA

By means of a careful history and physical examination, all patients in the two groups were definitely diagnosed as suffering from bronchial asthma. Scratch tests were made at first, and, in cases in which sufficient information was not secured, intracutaneous tests followed. Ophthalmic and nasal tests and passive transfer tests were carried out when indicated. Clinical experiments

with suspected allergens were made whenever possible and constitute our most authentic method of obtaining accurate information.

In addition complete blood counts, urinalyses and Wassermann or Kahn tests were routinely done, and the sputum was examined both for tuberculosis and for eosinophils. Most of the patients were examined with a fluoroscope and chest films were also taken in suspicious cases. Other laboratory tests e. g. electrocardiograms, basal metabolic readings and studies of the blood chemistry, were made in many of the cases.

In the course of the investigation, many patients, for various reasons, were not included. In some the diagnosis of bronchial asthma was in doubt. Those with silicosis, tuberculosis or definite cardiac disease were excluded even though true bronchial asthma may have coexisted. Patients who cooperated poorly also were not included in the study, and in a fairly large number of instances the present condition of the patient could not be discovered.

METHODS OF TREATMENT

The treatment, whenever possible is that based on the concept of allergy, namely elimination of the offending cause or causes, with great emphasis on the strictness of such elimination. This alone was sufficient in a number of cases. Hyposensitization, or desensitization, was carried out of those patients sensitive to allergens which cannot be completely avoided. These include such inhalant substances as pollen, molds, house dust,orris root, horse dander, feathers and cottonseed. Eggs, wheat and milk are so essential as also to deserve efforts at desensitization, either by the oral or by the hypodermic method.

But, when elimination and desensitization were unsuccessful, or in cases in which the causative factor could not be discovered, we were forced to use various non-specific measures. These are many and varied and time will permit only brief mention of a few. Epinephrine or aminophylline usually gives more or less relief from attacks. Other valuable drugs are ephedrine, the iodides, apomorphine, dextrose intravenously and ether by rectum or by inhalation. Vaccines, stock or autogenous, are often very helpful but probably act nonspecifically. Roentgen therapy, oxygen and helium, hyperpyrexia, instillation of iodized oil in the bronchi, bronchoscopic aspiration, surgery of the nose and sinuses and other procedures all have their advocates in selected cases. In one's enthusiasm for the allergic methods of treatment one must not overlook general hygienic measures.

More detailed observations on various methods of treatment will be found in such textbooks as that of Tuft,² they have also been dealt with in various papers.³

RESULTS OF TREATMENT

Follow-Up of Cases Previously Reported—In 1935 one of us (L. U.) reported on the results of treatment in a series of 207 patients with bronchial asthma who were under observation for a period of one to thirteen

years.¹ We now wish to discuss these same 207 patients with reference to their condition during the past seven years.

Table 1 shows the results of treatment in 1942 as compared to those in 1935. It can readily be seen that the percentages of those who obtained 100 per cent relief from symptoms for over a year or more were approxi-

You were under my care for Asthma in _____
As a part of an intensive study of Asthma. It becomes important to know what has become of you. I would appreciate it if you would answer the following questions as accurately as you can.

1 If you are cured when did the Asthma leave you? _____

2 Have you had any Asthma since I last saw you on _____?

If so how much trouble (mild, moderate, severe)? _____ What time of year? _____

Have you had to take injections or _____

Are you exposed to animals if so kind _____?

Do you sleep on feather pillows? _____ Rubber covered? _____

3 Have you taken or are you taking treatment for your Asthma from some other

physician _____? If so what sort of treatment _____?

What results _____?

Have you had any surgical operation for Asthma _____?

If so what kind and what results _____?

4 Have you at any time changed climate because of Asthma _____?

If so for how long where did you go and what were the results _____?

_____?

In any case I am anxious to know about you and I ask that you write any additional information about yourself and your Asthma on the back of this letter. All this will be of great service to those who suffer from Asthma. I would appreciate it if you would return this letter and answers promptly to me in the enclosed stamped envelope. What is your present address?

Yours sincerely

ber of deaths, many of which were not due to asthma, had increased during this period of seven years.

Table 2 analyzes the follow-up in each group. This shows that almost all of those who were entirely symptom free in 1935 were still entirely or almost entirely relieved. One of the 2 who died was accidentally killed, and the other died of lobar pneumonia. Unfortunately, we are unable to trace 9 of these 45 patients.

Nineteen of the 104 patients previously classified as improved have by now been symptom free for over a year, but 4 are worse and 6 have died. Of the 37 patients previously reported as unimproved, only 9 are now improved and 8 have died.

The best results were obtained in youngsters and especially in those in whom the offending cause was found and eliminated.

Survey of Entire Group of 459 Cases—In addition to the 207 patients just analyzed, an additional 252 patients have been added, this making a total of 459. The second group has been under observation for from one to eight years.

In the 1935 report, we divided our cases into "extrinsic" and "intrinsic," in accordance with the suggestion of Rackemann. An "extrinsic" patient is one who has been found hypersensitive to one or more allergens. All patients whose causative allergens were not discovered were placed in the "intrinsic" group, wherein it is

Unimproved	37	1	8	19	8

thought that the asthma is due to something within the body, possibly bacteria. The best results were naturally found in the "extrinsic" group.

In the present study we have classified the patients as "paroxysmal" or "chronic," because we believe that this grouping is superior in that it can be made at the time of the first visit and because it indicates a much more accurate prognosis than any other classification. Our good results are usually obtained in the paroxysmal group. Chronic asthma is often complicated by emphysema and chronic bronchitis. While it is true that most patients with paroxysmal asthma show definite positive cutaneous reactions and are therefore classed as "extrinsic," this is not always the case, since some of these patients classified as "extrinsic" have acquired chronic asthma.

Table 3 refers to the sex and age of onset in the entire group. For some unknown reason males predominate in the paroxysmal group and females in the chronic. The most outstanding observation is the high incidence of paroxysmal asthma in the first decade, comprising 144 of the 459 cases. The number of paroxysmal cases diminishes as age increases, and cases are

uncommon in the age group past 50, on the other hand, chronic asthma occurs at all ages, even in patients whose asthma begins in the first ten years of life.

The results of treatment are found in table 4, which reveals that the number of those who obtained 100 per cent relief from symptoms was far greater in the paroxysmal group, 93 to 4, likewise, this group included 173 patients who were improved as compared to 72 in the chronic group. Death was much more common among the chronic group, 37 of 161 patients with chronic asthma died, an incidence of approximately 23 per cent as opposed to only 11 of 298 patients with paroxysmal asthma (3.7 per cent).

One also notes that the best results are obtained in those whose paroxysmal asthma begins in the first decade of life. The prospect for complete relief or improvement lessens with increasing age although the table shows that this is not entirely true in each decade. The prognosis is especially good for paroxysmal asthma in the age group 20 to 29.

Table 5 summarizes the cause of death in the 48 cases. In 21 instances, death was known or presumed to be due to asthma. When a patient with severe asthma died and the cause of death was not stated and there were no other known contributory factors, asthma was presumed to be the cause of death. This may, of course,

TABLE 3—Sex and Age of Onset of 459 Cases of Bronchial Asthma (Entire Group)

Age at Onset	Paroxysmal		Chronic	
	Male	Female	Male	Female
0-9	95	49	13	25
10-19	10	98	12	16

40-49	10	14	15	14
50-59	3	2	7	10
60-69			2	2
Totals	150	130	62	98

not be correct, and our percentage in this group is probably too high. Sixteen patients died who had both asthma and some other serious condition, e. g. hypertension, cerebral hemorrhage, pneumonia or cardiac decompensation. The asthma of the other 11 patients had been entirely or almost entirely relieved and they might well be classified in the 100 per cent or improved group, but death occurred from some cause other than asthma, e. g. accident, pneumonia, meningitis, carcinoma or bleeding peptic ulcer.

In the first group of 21 who died during asthmatic seizures morphine was known to have been injected in 6 shortly before death, and one may well believe that others in the group may also have received this drug. Autopsy on 2 of those who received morphine revealed almost complete blocking by mucous plugs of the smaller bronchi and bronchioles. Our own experience and that of others has led us to the conclusion that morphine should never be given during an attack of bronchial asthma. Morphine probably kills patients with asthma by depressing the cough reflex so that they cannot cough up the sticky sputum which blocks the air passages, it probably harms also by depressing the cerebral respiratory center and, in some instances, by a hypersensitivity to the drug. We might add that since we abandoned the use of morphine some ten years ago no patient under our care has died of asthma.

Table 6 summarizes the results of therapy in 459 cases. Ninety-seven of the patients obtained 100 per cent relief (21.1 per cent), 245 patients showed improvement varying from 25 to 95 per cent (53.3 per cent), 69 patients were unimproved (15.1 per cent), and 48 were dead (10.4 per cent). The excellent results obtained in the paroxysmal group are clearly shown.

REVIEW OF THE LITERATURE

The task of gathering statistics as to results of treatment in large series of cases is so great that very few reports can be found. The early studies of Walker,⁴ Larsen and Bell,⁵ and Rowe⁶ either gave no tables of results or the duration of observation was less than one year which we believe to be the minimum requirement. Menagh⁷ in a study of 300 patients with asthma reported that 85 were well, 83 improved and 38 not improved. He states that surgery of the nose and throat cleared up 31 per cent of his cases and that vaccines aided another 44 per cent. Browning⁸ in a series of 244 cases of bronchial asthma obtained 95 to 100 per cent relief in 89 instances and 75 to 95 per cent

TABLE 5—Causes of Death in Bronchial Asthma

asthma begins in the first ten years of life are, like those of ours, much the best obtained in any decade

Claude⁹ states that thoracic deformity is especially common when asthma begins during infancy. While Edrington¹⁰ gives no definite statistics, he does say that results obtained by the present day treatment are a vast improvement over those obtained twenty or thirty years ago and that the outlook for the asthmatic patient is not nearly as hopeless as it was in former years. Time and a better understanding of many factors concerned will still further improve our results. Copeland and Keating¹¹ obtained good results in 80 per cent of 58 children with pollen asthma and hay fever.

We are especially indebted to Rackemann for his surveys as to results of treatment. In 1927 he reported a series of 1,074 private and clinic patients with asthma who had been followed for at least two years.¹² His results were about the same as ours, i. e. about 20 per cent of his patients are in the "cured" class, another 50 per cent are more or less improved, about 20 per cent are no better, and the other 10 per cent are dead. In his series, as in ours, the percentage of "cured" and improved patients is high among those whose asthma begins in the first decade and decreases with each decade. In both series the best results occur in those cases in which the cause can be found and can be eliminated.

In 1928¹³ and in 1932¹⁴ Rackemann reviewed his so-called cured group and found that 49 of these 213 patients had had a relapse. From this it is apparent that Vander Veer¹⁵ was probably correct when he stated that "once an asthmatic, a patient is usually a potential asthmatic for the rest of his life." Or, as Rackemann puts it, "the results in the extrinsic group show that cure has been accomplished by the removal of the trigger which fired the attack, but obviously the gun remains loaded in most and probably in all cases. Fundamental allergy is evidently a remarkably persistent trait."

The good results reported in this country by many observers are apparently not obtained by some in other lands. Witts¹⁶ of London stated that after five years of work at the asthma clinic he was very much dissatisfied with the treatment of asthma. He said, "Many American books on allergy read like a detective story. One sees the allergist studying the most intimate details of the patient's life, entering his bedroom and holiday camp, placing in position his greased slides and Petri dishes, estimating the leukopenic index and supervising an elimination diet until the offending allergen is tracked down. Like psychoanalysis, it makes exciting reading, but it is difficult, if not impossible, to apply on a large scale in practice. In any event, the detection of allergens is very different from the cure of asthma." Most of us, I am glad to say, do not agree with these amusing remarks.

COMMENT

Despite the probability that the tendency to asthma continues to exist in all asthmatic patients, one must not be downcast. On the contrary, we have shown that by the allergic method of treatment, if carefully supervised and if coupled with good hygienic measures, the results obtained are often phenomenal and long lasting. Not 1 of 36 patients reported as being entirely symptom free in 1935 had a relapse to any extent in the past seven years, and many of the patients previously reported to have improved are now free from asthma.

The outstanding finding in these and in similar studies has been the excellent results obtained in those whose asthma starts in early life, and especially in those whose causative factor has been removed. When we compare the paroxysmal group with the chronic, we are struck with the great difference between the two. The results in the paroxysmal group are excellent, as contrasted to the results in those in whom symptoms are more or less constant. Improvement occurs in about half of the chronic cases, but complete relief is rarely obtained.

It would seem, then, that three important observations can be made. In the first place, one should try to prevent the very onset of asthma, this is especially successful if children of allergic parents are shielded from known causes of asthma, e. g. pets and feather pillows. Second, if allergic symptoms begin, cutaneous tests and other methods of allergic survey should be carried out at once, it is sheer folly to wait until chest deformities, bronchitis and emphysema occur and the symptoms have become chronic. Lastly, since allergic persons may suffer a relapse, they should be kept under observation as long as possible. They may not need treatment but they should not be discharged. They should report for reexamination every few months at first and then perhaps once a year. Patients are very apt to become careless of their environment or diet.

SUMMARY AND CONCLUSIONS

1. A follow-up study in 207 cases of bronchial asthma revealed that after an additional seven years almost all patients who previously were symptom free were still in excellent condition. Nineteen of 104 patients previously reported as improved are now 100 per cent relieved, and a few are worse or have died. Those who were unimproved in 1935 were for the most part still unimproved or had died.

2. In addition to these 207 cases, an additional 252 patients have been added to the study, making a total of 459 patients who have been under observation from one to twenty years.

3. Because of the simplicity and because of the more accurate prognosis, the cases have been classified as "paroxysmal" and "chronic." The paroxysmal cases occur chiefly in early life, but chronic asthma is prevalent at any age.

4. Ninety-three of the 298 patients with paroxysmal asthma obtained 100 per cent relief from symptoms as compared to only 4 of the 161 patients with chronic asthma, the percentage of improvement was also much higher in the paroxysmal group, while death occurred in 23 per cent of the chronic cases as contrasted to only 3.7 per cent in the paroxysmal group.

5. The best results are obtained in those who have paroxysmal asthma caused by some allergen which can be found and which can be eliminated. Symptoms in these successful cases are apt to begin in the first decade of life.

6 Death occurred in 48 cases, or approximately 10 per cent of the entire series. Of these, asthma was the sole or main cause in 21 cases and was a contributory factor in another 16 instances. The other 11 fatalities occurred accidentally or from disease not related to asthma.

7 Morphine was known to have been given prior to death in 6 cases, and probably caused death by preventing the expulsion of obstructing mucous plugs. Since we have abandoned the use of morphine several years ago we have not had a fatality due to asthma.

8 To prevent chronic asthma, with its relatively poor prognosis, preventive measures should be instituted in the children of allergic parents, and an allergic survey should be made at once if symptoms begin.

ABSTRACT OF DISCUSSION

DR RALPH G. MILLS, Decatur, Ill. There is no such thing as a normal lung unless one accepts as normal the organs of an infant at birth. Immediately after birth the lung becomes the scene of conflict between invading bacteria and the tissue protecting mechanism. The changes that result from this and similar assaults make it possible for asthma to develop in certain individuals. Asthma does not appear immediately after birth but at a somewhat later date. This may be a few months or it may be many years. Sufficient time must have elapsed for organic change to take place as well as disturbed physiology. In some way H substance, perhaps histamine, is formed during antigen-antibody contact and thus is initiated the sequence of events called asthma. The neutralization of this substance and the elimination of the product of its action—mainly mucus—is the ultimate aim of treatment. The earlier this is accomplished, the lighter the attack. I wish the authors had presented more in detail the methods employed in counteracting the effects of histamine. One might roughly classify the methods enumerated into two groups. All those are good that loosen the mucous plugs in the bronchioles, and those are useless that fail to do so. Morphine is properly placed in the latter class. I am none too sure about oxygen and helium. They relieve distress, it is true, but chiefly by reducing the tendency to cough, a mechanism by which drowning is avoided. Iodized oil introduced into the bronchi does not arouse my enthusiasm. The mention of intravenous dextrose is proper, for there is much evidence that blood sugar levels may run quite low at times. An attack of asthma is a physical ordeal, and the body needs additional calories. No mention was made of glandular therapy. I feel that thyroid should surely be mentioned, and possibly also adrenal and anterior pituitary. The results of treatment are seemingly better in the second period than in the first. Definite progress is being made in therapy, and it is to be expected that later reports will be even better.

DR GEORGE F. HARSH, San Diego, Calif. A study like this is especially valuable, because I find among my colleagues a most distressing pessimism about the results of treatment of allergic disorders. The authors properly warn against the use of morphine. I was trained in a school which taught that you should never use morphine in a case of asthma. I experimented gingerly and I believe I have detected a certain small group of asthmatic patients for whom the use of morphine is justifiable, and that is the type of patient who is going along perfectly normally and then suddenly gets a violent attack of asthma. He is terrified. He thinks he is going to die. Epinephrine will relieve him partially, but he is still almost literally scared to death. A small dose of morphine may completely abort that patient's attack. If it comes back as soon as the effect of the opiate has worn off, morphine should not be repeated. Some physicians use apomorphine. I should like to ask the authors whether there is not the same danger with apomorphine as with morphine. There is one other drug that is at least as dangerous as morphine, and that is atropine. The one asthmatic patient for whom I had the misfortune of officiating at

death was given atropine. This patient incidentally was also unable to tolerate iodides so that adequate treatment of his asthma was seriously hampered. One method of treatment which is conspicuous by its absence in this discussion is "change of climate." That seems to be the treatment *par excellence* in the mind of the public and in the minds of many physicians. I live in a part of the country where we get a great many patients for whom this treatment has been advised. A change of climate is a drastic form of treatment. A man who is established in a community has to leave his friends and his job and dispose of his property at a loss. The very type of patient who would be a candidate for such a drastic form of treatment is the one who is likely not to benefit by it. In other words the patient with severe asthma is the one who is apt to become sensitive to whatever there is in the environment to be sensitive to. After a change of climate he may for a short time show some improvement, but soon the old condition will return.

DR HERBERT F. ROBB, Belleville, Mich. I believe the older practitioner will recognize that there are more cases of asthma today than there were twenty-five years ago. In the etiology of asthma we recognize the hereditary factors along with others in the cause of allergy. We should also recognize that asthma is a psychosomatic disease and as such is under a greater influence in our urban civilization than it was back in the agricultural era. When we consider that the individual is developed from the union of two microscopic cells planted in the uterus of the mother, grown there for nine months and then cast out into a misunderstanding world, we cannot help but realize the innumerable and varied environmental forces to which the human organism is subjected. Before and after birth the individual is dominated by five forces: hunger—hunger for air, water, food and chemicals, sex, a force which becomes dominant in the parents and individual at the age of puberty; intelligence, which may be negative or positive, and social and economic forces which are positive or negative. In asthma of the child we may consider that it is possibly the functional and organic result of a psychosomatic problem in the parents. In the urban centers there is a reduced birth rate and the greater problem of birth control. It would be well in our study of the etiologic factors in the cause of asthma to consider the sex problem between husband and wife to discover any psychic conflicts or sexual maladjustments which may be factors in the development or exacerbation of this disease.

DR LEON UNGER, Chicago. There are three schools of thought with relation to allergy and psychoneurotic disturbances. There are those who believe that the psychoneurotic effects are most important, those who pay no attention whatsoever to them, and those who believe that the psychoneurotic influences do play a part. I belong to the latter group. There is no doubt that psychic and neurotic influences increase the severity and the frequency of attacks of asthma but I deny emphatically that psychosomatic influences can initiate asthma. In treatment we must make every effort to reduce the psychosomatic disturbances in order to reduce the frequency and severity of the attacks. The role of histamine or H substance in asthma has never been proved. We believe that, when the antigen-antibody contact is made, something similar to histamine is elaborated. It probably is some substance which is related to histamine to which the name H substance is given. Dr. Mills spoke of the method of neutralizing this substance. That is theoretical. However, his point of dividing the methods for counteracting histamine into those which loosen mucus in the bronchioles and those that do not is good because death in asthma and the symptoms in asthma are definitely due to the obstruction in the bronchioles, and anything one can do to increase the lumen of the bronchioles is beneficial to the asthmatic. Morphine may kill the patient because it prevents the expulsion of these mucous plugs. As to the role of oxygen and helium, I too am not sure. We use it in our hospital in Chicago. Helium conveys the oxygen more readily into the bronchioles. I used iodized oil for treatment years ago but have stopped using it. Dextrose intravenously is excellent for two reasons. First of all it is nourishing and second, in severe cases the addition of 1 cc. of 1,000 epinephrine into a liter of 5 per cent dextrose often gives good results. The use of the endocrines

has been disappointing. Solution of posterior pituitary has not given good results. We advise change of climate if a patient has been under treatment for six months or a year and has followed the treatment intelligently but still has asthma. I want to emphasize two things. Don't use morphine in bronchial asthma, use it in cardiac asthma. Second, see these patients early, before their condition becomes chronic, and good results will follow, but if one waits until they are in the chronic stage, one will have a problem on one's hands.

PULSATING EXOPHTHALMOS

REVIEW OF ALL REPORTED CASES

J. D. MARTIN JR., M.D.
AND

ROBERT F. MABON, M.D.
ATLANTA, GA.

Unilateral pulsating exophthalmos was first described by Benjamin Travers in 1809¹. Since then there have been approximately 812 cases reported in the literature. Any retrobulbar mass may produce an exophthalmos, but usually vascular disease is the basis for the pulsating form. The bruit and pulsations of the orbit usually occur from the synchronous movements of the blood through an arteriovenous fistula. These pathologic processes have been verified by many autopsies.

An attempt is being made to present evidence justifying the diagnosis of these conditions and to report a series of cases. A complete summary of all additional reports since Locke's review is submitted.

Travers's conception of the etiology was incorrect, although it was realized that compression of the common carotid caused a cessation of the bruit and a decrease in the degree of the exophthalmos. In 1812 Dalrymple reported a second case of this nature. Before 1823 it was believed that the condition was due to a cirroid aneurysm, but Guthrie found at autopsy an aneurysm of the ophthalmic artery. In 1835 a new theory was formulated by finding at autopsy a communication between the cavernous sinus and the internal carotid artery. Warren in 1837 described the first case which was produced by trauma. Burke in 1839 confirmed Guthrie's findings in a second autopsy. Nunneley in 1862 believed that the etiologic factor was such a fistula. In 1880 Sattler concluded from a review of the literature that the cause was due to an abnormal arteriovenous communication. De Schweinitz and Holloway in 1907¹ reviewed and clarified the reports of these conditions. Locke¹ in 1924 made a complete review of the literature to this date and summarized the methods of treatment.²

ANATOMICAL DISCUSSION

The majority of the cases of pulsating exophthalmos are unilateral. The most frequent causes of a nonpulsating unilateral exophthalmos are retrobulbar tumors of soft tissues, bony orbital tumors or vascular lesions such as varicocele of the ophthalmic veins. Infections of the sinuses, soft tissues and bones of the

orbit may produce an exophthalmos. Prominence of the eye may occur as a result of an anterior staphyloma or a high myopia.

The pulsating form usually follows trauma and is the result of a fistula between the internal carotid artery and the cavernous sinus. In some instances a fracture through the base of the skull involving the body of the sphenoid may be demonstrated. It is in this relatively immobile area that the greatest damage to the vessels occurs. Pulsating exophthalmos may result from penetrating wounds in this region. Spontaneous cases may occur from rupture of the artery within the sinus, caused by arteriosclerotic plaques, miliary septic aneurysms or congenital weakness of the vessel wall.

The relations of the internal carotid artery and cavernous sinus are peculiar in that they constitute the only example of an artery lying within and entirely surrounded by a venous channel. This arrangement may permit the formation of arteriovenous fistulas with a minimum of trauma.

The cavernous sinus is an irregularly shaped venous space situated between the meningeal and periosteal layers of the dura mater on the side of the body of the sphenoid bone.³ It extends from the medial end of the superior orbital fissure in front to the apex of the petrous portion of the temporal bone behind. Its lateral wall contains the oculomotor and trochlear and the ophthalmic division of the trigeminal nerves, in order from above downward. The internal carotid artery and abducens nerve are contained in the thinner medial wall of the sinus. The two cavernous sinuses communicate across the midline by the small intercavernous sinuses situated before and behind the hypophysis.

The internal carotid artery enters the floor of the base of the skull through the foramen lacerum in the temporal bone (ensheathed by a prolongation downward of the dura).

Turning forward, it traverses the cavernous sinus, separated only by a covering of endothelium. Near the anterior end of the venous space, it curves upward along the medial side of the anterior clinoid process, gives off the ophthalmic artery and perforates the dura mater again to unite with its fellow of the opposite side in the circle of Willis. The ophthalmic artery enters the orbital cavity through the optic foramen below and lateral to the optic nerve.

Anteriorly the two ophthalmic veins lie within the orbital cavity and join the sinus either separately or by a common trunk.

Posteriorly the cavernous sinus is drained through the superior and inferior petrosal sinuses, which in turn empty into the lateral sinuses.

The pathologic physiology of pulsating exophthalmos resulting from an arteriovenous fistula in the cavernous sinus is apparent. There is a difference in pressure in the two vascular channels and the venous communications of the sinus. A rupture results in a sudden engorgement of the venous space with arterial blood under high pressure. There is a retrograde flow into the ophthalmic veins, with transmitted arterial pulsations and a venous engorgement of the orbital contents and eyelids. These changes may occur to a less degree on the opposite side as a result of the aforementioned communications between the two cavernous sinuses.

carotid on the same side. In many cases there is sufficient collateral to bring about incomplete regression or recurrence of symptoms.

DIAGNOSIS

The diagnosis of unilateral exophthalmos is usually easy depending on the degree of proptosis. It has been noted in many cases that pulsation does not always exist. In those which occur spontaneously, pulsation may be absent. Following head injuries a bruit, thrill and pulsation usually are present. The symptoms most often encountered are headache, disturbance in vision and intraocular noises. The sounds may vary from minor sensations to an almost continuous roaring. The visual field may show a wide range of disturbance. Diplopia may result from an increase in internal or extraocular pressures. The presence of chemosis accounts for some of these changes. Blindness may be due to atrophy of the optic nerve, to glaucoma or to cataract.⁴

The extrinsic movements of the eye are limited by the proptosis and the alterations in the nerve mechanism of the extraocular muscles. The retinal findings are not constant and depend on the duration of symptoms. Compression of the common carotid artery will result in a cessation of a bruit, thrill and pulsation when present. Arteriograms⁵ may be obtained by the injec-

REPORT OF CASES

CASE 1—E. C., a Negro aged 62, admitted to Emory University Division of Grady Hospital, Dec. 26, 1940, was struck by an automobile in October 1940 and was temporarily unconscious. He was seen immediately in the outpatient clinic and at that time had regained consciousness. A small scalp wound was then sutured. There were no complaints until November, when he heard a loud noise in his left ear which was synchronous with the heart beat. Soon afterward his left eyelid gradually increased in size until he was unable to close it. There were no visual defects. A definite chemosis of the left eye was noted with a protrusion of the orbital contents, which did not pulsate. Extraocular movements were well performed. Both pupils were round, regular in size and reacted to light. There was a moderate thrill and bruit heard over the left supraorbital ridge. Roentgenograms of the skull revealed a long, linear fracture arising in the region of the left frontoparietal bone near the junction of the sphenoid. Blood pressure on admission was 150 systolic and 70 diastolic. Daily digital compressions of the left carotid artery were begun. Following this there was a slight decrease in the swelling and chemosis of the eye.

A partial occlusion of the left common carotid artery was made with an aluminum band. On Jan. 21, 1941 the left common carotid artery was ligated with braided silk. proptosis

Fig. 1 (case 1)—Exophthalmos with pronounced chemosis before operation.

to the site of the previously applied band. No evidence of cerebral anemia was manifested following this procedure. The bruit was inaudible and the chemosis almost subsided. Two months later no return of symptoms had been noted.

CASE 2—F. S., a Negro aged 24, admitted to Emory University Division of Grady Hospital, July 26, 1936, was struck over the right eye when he was overturned in a truck on May 2, 1936. He received a small abrasion over the eye but did not lose consciousness. A swelling was present on the upper eyelid which continued to increase in size. About a month before he was admitted to the hospital the lower lid became swollen and edematous. The patient complained of a continuous noise within the cranium. Physical examination was negative except for the right eye. There was definite proptosis with a protrusion of the lower bulbar conjunctiva. Movements of the eye were somewhat slow. The pupils were round and active, but the right was slightly larger and more sluggish. Tension in the right eye was 25 mm. and in the left eye 20 mm. In the right fundus was a large flame-like hemorrhage on the upper and inner disk margin. The veins and artery ratio was 4 to 1 but no pulsations were noted. There was sclerosis in the retinal vessels more pronounced in the superior nasal artery. The left fundus was essentially negative except for a slight sclerosis. The vein and artery ratio in the left eye was 3 to 2. Vision was good in both eyes with no disturbances in the visual fields. A loud bruit was audible over the right eye which disappeared on compression

of the right common carotid artery. The blood pressure in the right arm was 150 systolic and 102 diastolic. In the left arm it was 120 systolic and 80 diastolic. X-ray examination of the skull revealed a linear fracture passing from the region of the upper portion of the right supraorbital ridge obliquely upward and through the lower anterior portion of the right

Fig. 2—Anatomic section demonstrating internal carotid artery in the center of the cavernous sinus, also showing relative position of nerves in sinus wall.

frontal bone. There was no comminution or depression of these fragments. An area of increased density was visible in the region of the right orbit and optic foramen.

The contours of the superior orbital fissures were obliterated. Periodic digital compressions were instituted to increase collateral circulation within the brain. On August 4 the right internal carotid was ligated with two heavy braided silk ligatures. The bruit immediately stopped. Convalescence from this procedure was uneventful.

CASE 3—J. T. B., a white man aged 43, admitted to Emory University Hospital on Nov. 3, 1938, stated that the

Fig. 3—Relationship of the sinus to the arteries and nerves and the reflections of the dura.

left eye suddenly became swollen eight months prior to admission and began to protrude from its normal position. Shortly after this a roaring was noted which could be controlled by pressure on the left side of the neck. The patient complained of severe headaches and had been treated for hypertension several months before the onset of the exophthalmos. There

was no history of trauma. Physical examination was essentially negative except for hypertension. The blood pressure in the left arm was 170 systolic and 114 diastolic. In the right arm the blood pressure was 180 systolic and 110 diastolic. The left eye protruded definitely. There was a chemosis and engorgement of the conjunctival vessels. Compression was applied for five minute intervals on the left common carotid three times daily for about a week. On November 8 he was operated on by Dr. D. C. Elkin. The left common carotid artery was completely occluded by an aluminum band. Postoperative convalescence was satisfactory. The exophthalmos improved considerably but the venous congestion in the conjunctiva still remained. At the present time no change in his condition has been noted.

CASE 4—E. M., a white man aged 22, admitted to Emory University Hospital on March 7, 1936, had been in an automobile accident six months before. Following this a roaring noise was heard in the right ear. There was a swelling of both eyes, more pronounced in the right. The exact nature of the injury was not determined at the time of the accident, and the patient did not interrupt his usual activities.

The patient was well developed and well nourished and appeared normal in every respect except for the eyes. There was some edema of both eyes, the right being more prominent.

Fig. 4 (case 5)—Tortuosity of vessels occupying the orbital fossa.

with edema of both upper and lower lids. The ciliary vessels of the right eye were engorged. Vision was not affected. The fundi were normal except for venous engorgement. Pulsations of the eye were not present. A thrill was felt and a bruit was heard over the entire skull, most pronounced over the supraorbital region on the right side. The blood pressure was normal. It was thought that the patient probably had a traumatic arteriovenous fistula involving the cavernous sinus.

Preliminary preparations were made for ligation of the carotid artery by compression of the vessels in the neck to stimulate collateral circulation in the brain. After about ten days, on April 27, ligation of the right internal carotid artery was done. A small Matas aluminum band was placed around the internal carotid artery, which completely compressed it at the bifurcation of the common carotid artery. There was an immediate cessation of the thrill and bruit in the region of the right eye. No untoward symptoms were noted. For some time the patient noticed that on severe exertion a numbness occurred in the left side of the body, which disappeared on resting. No motor symptoms were ever exhibited. His condition in July 1941 was still unchanged.

CASE 5—J. D., a white man aged 33, admitted to Emory University Hospital on July 8, 1940, was shot in the left eye thirteen years before and removal of the eye was necessary. Six years before admission he noticed a mass beneath the eyelid which had gradually increased in size. On examination there was a mass which filled the entire orbital fossa and protruded from beneath the lid about 3 cm. There was a definite dilata-

tion of the superficial vessels both on the surface of this mass and also to the outer side of the orbital fossa. There was a palpable thrill and bruit heard over this area. This was stopped by pressure over the common carotid artery. The remainder of the physical examination was negative. On July 12 a partial occlusion of the left common carotid artery was made with a metal band by Dr D. C. Elkin. Three days later the artery was completely occluded with heavy braided silk. On July 15 the entire mass of veins and arteries were removed through an incision beneath the lid. There were multiple communications between the ophthalmic arteries and veins. Convalescence was uneventful except for some purulent drainage, which had cleared up on Aug. 1, 1940, when he was dismissed from the hospital.

This case presents an example of traumatic unilateral exophthalmos with symptoms usually seen in ones involving the deeper structures. The previous removal of the eye permitted a more accessible approach to the arteriovenous fistula and allowed for the usual treatment for such conditions.

TREATMENT

The treatment of arteriovenous aneurysm of the cavernous sinus and the branches of the internal carotid artery cannot necessarily be approached in the manner for similar lesions elsewhere. The usual treatment for arteriovenous aneurysms is quadruple ligation with excision of the aneurysmal sac. It is obvious that the anatomic location prohibits any such procedure. Many approaches have been made to this problem, none of which are based on good reasoning. Proximal arterial

Various methods of occluding the vessels have been attempted, extending from digital compression to external occlusions of the common and internal carotid with an apparatus similar to the type described by Matas.⁶ Partial closures have also been made with aluminum bands, fascial grafts and other types of surgical liga-

Fig. 6 (case 5)—Arteries and veins after removal

tures such as tape and silk and, more recently, the use of cellophane.⁷ The latter is used for partial occlusion. This is based on the belief that when cellophane is used it is followed by a gradual constriction. It is hoped that partial constriction may become complete after a short time. This gradual closure may lessen the likelihood of the production of cerebral aneurysm. Dandy⁸ has devised as nearly a surgical approach to this condition as is done in ordinary arteriovenous aneurysms. His procedure is to occlude the artery as it emerges to form the circle of Willis with metal clips to obliterate the blood supply at the fistula. A previous study of the anatomy, however, has shown that the blood supply is derived, both proximally and distally to the arteriovenous communication, from one side, as well as from the face, through the communicating veins. It is also derived through the communications of the arterial supply from the circle of Willis on the opposite side. Therefore unless a complete extirpation of the aneurysm is made along with total ligations a cure should not be effected. Dandy reports satisfactory results using such a procedure.

Fig. 5 (case 5)—Position of arteriovenous fistula

ligations have been done in the majority of instances and with the greatest benefit. The common carotid artery has been ligated, as well as the internal and external, individually and concurrently. Carotid ligations have also been carried out on the contralateral side. These have been performed singly as well as simultaneously, depending on the results obtained.

Arterial plugging⁹ has been attempted by the injection of paraffin into the carotid artery with the hope that it would obliterate the arteriovenous fistula. Muscle plugs¹⁰ have also been inserted into the artery for the same reason. These procedures for the most part have been discarded because they have not proved beneficial. Various forms of medical therapy have been undertaken. The administration of gelatin to increase the coagulation of the blood, with the idea of slowing the blood flow through the fistula and allowing thrombus formation, has been given consideration. Treatment has been directed toward the extirpation and obliteration of the veins.¹¹ Electrocoagulation¹² and sclerosing agents have been used to promote thrombosis of the orbital veins. The use of these procedures has not been universally adopted. In the advanced cases in which the eye has been lost, evacuation of the orbital contents has been carried out. At the time of this procedure an attack can be made on the fistula from the apex of the orbit. The exposure here is inadequate for proper surgical approach.

The treatment which probably offers the most to the patient is, first, preoperative digital compression of the carotid artery. This is undertaken for the purpose of stimulating collateral circulation, preventing the development of cerebral anemia after ligation of the carotids. The procedure should always be attended with the knowledge that some individuals may have a hypersensitive carotid sinus reflex.¹³ Pressure could result in a syncopal attack or perhaps a more serious outcome. Therefore initial compression of the artery should be done with extreme care to determine the patient's reactions. These develop immediately after compression, whereas the symptoms of cerebral anemia occur late.

There is little evidence to substantiate the preference of ligation of the internal or common carotids. The latter is more commonly ligated, probably because it is more accessible. A reflux flow from the contralateral vessels through the external carotid may result in a failure of cure. If partial ligation is done it may be necessary to occlude the vessel totally after the danger of cerebral anemia is over. When an aneurysm has been present for a long time, sufficient collateral circulation will usually be established from the opposite side through the circle of Willis. Cases not benefited by ligation may be improved by a direct approach advocated by Dandy. In view of the number of cases improved and cured by proximal ligations alone, this preliminary procedure should be carried out in all instances. The results offer little support for medical therapy in the progress and termination of these conditions.

SUMMARY OF REPORTED CASES

There have been one hundred and sixty-three articles in major journals on pulsating exophthalmos since Locke's review in 1924, 224 additional cases have been reported through December 1941. Essentially all reports deal with the same problem previously discussed by Locke and others. It is noted that the choice

of treatment is primarily operative. Ligation of the internal carotid was performed in 47 cases, of this number 25 were reported as cured. The common carotid was ligated in 43 instances with cures in 30. The ligation of multiple vessels, a combination of either the internal, external or common carotid and orbital veins, was carried out in 41 cases with twenty-seven cures. It is evident from such a summary that the results in all types of treatment are the same. The greatest contribution since 1924 has been, perhaps, the work of Dandy in ligating intracranially the carotid artery for the purpose of trapping the aneurysm. This procedure has been carried out six times, with 4 cases being reported as cured. It is advisable in many instances to undertake this operation when other methods fail.

CONCLUSION

In this report a complete review of the literature since 1924 has been made. This brings the total reported cases to 812. Five additional operative cases are submitted by us. An explanation for the development of these conditions is made on the basis of anatomic studies of the cavernous sinus. This is the only example of a major artery within and a part of a large venous channel. Any trauma or disease to the artery would therefore allow an interchange of arterial and venous blood between these structures, thus an arteriovenous fistula would be formed. Basal fractures involving this area should be attended with the thought that a fistula may occur. In view of the progress of the disease, early treatment, namely ligation of the carotid artery, should be undertaken before extensive proptosis develops. This would decrease the danger of further destruction and blindness. Surgical treatment is beneficial, although many cases are followed by slight improvement and sometimes no change. There is no satisfactory direct operation to obliterate the fistula. This primarily is due to its location and association with vital structures.

ABSTRACT OF DISCUSSION

DR HARRY H. KERR, Washington, D. C. Pulsating exophthalmos is a symptom most commonly seen in fractures of the base of the skull passing through the anterior fossa. Ligation of the common carotid artery is the best treatment. I thought we could demonstrate a direct connection between the external and internal carotid arteries intracranially. Moss and King of the Wilmer Ophthalmological Institute at Baltimore have recently shown that there is a very free communication between the external carotid artery and the ophthalmic artery. My first patient was a righthanded man aged 42 with pulsating exophthalmos of the left side. Digital compression of the common carotid demonstrated that complete occlusion promptly led to difficulty with speech and with the use of the right hand. Partial compression, however, reduced the bruit and the pulsation without producing cerebral symptoms. We therefore hit on the idea of fractional ligation. Under local anesthesia, with the patient conscious and able to cooperate, we exposed the left common carotid artery, placed a fascial band around it and constricted the artery down to a position where he had no cerebral symptoms and no disturbance of speech or function of the right hand. We then fastened the band in situ. We found that we had occluded the artery about 50 per cent. The wound was closed, and two weeks later, after experimenting with compression again, we ligated completely the common carotid artery. I reexamined this man nineteen years later and made a complete ophthalmologic study. He had remained completely cured, and his eyes were perfectly normal for a man then aged 61. I have since operated on 7 additional patients with similar results and have found that the late return of a slight bruit best heard in the neck was due to recanalization of the common

carotid artery, so that now, in the last few cases, in addition to fractional ligation I divide the artery. Six of the 8 cases were the result of fractured skull. One was a spontaneous pulsating exophthalmos in a woman of 73 and 1 case was due to gunshot wound from birdshot in which the other eye had been destroyed. Secondly, ligation or division was carried out on an average of sixteen days after the first partial ligation.

DR. ALTON OCHSNER, New Orleans. There are two points that I should like to emphasize. Occasionally one will find persons whom ligation of either the internal carotid or the common carotid will not help. In such instances it is necessary to combine ligation of the carotid with the intracranial clip, as suggested by Dandy. Recently Dr. DeBakey has shown that the gradual occlusion of the artery by cellophane does not work. In an extensive experimentation he was unable to verify Pierce's work concerning this. He has had 2 patients on whom, in an attempt to increase the intracranial vascularity, he has done a sympathectomy. One of these persons was greatly improved following the sympathectomy. This is based on the observations of Gage that in patients with peripheral arteriovenous aneurysms, by decreasing the peripheral resistance and by increasing the vascularity, the aneurysm can be attacked with impunity. One of these patients was definitely improved following the sympathectomy, so that the ligation could be done safely. The other patient was cured by sympathectomy, simply indicating that by slowing the blood stream through the arteriovenous anastomosis, clotting was made possible, so that I think in the older person in whom hemiplegia is likely to occur, the use of cervicodorsal sympathectomy is of value and should be tried.

DR. JAMES RUDOLPH JAEGER, Denver. It is obvious if we remember the anatomy concerned in the carotid-cavernous arteriovenous communications that a good many of these cases will not be cured by ligating the carotid in the neck or intracranially because the internal carotid has branches inside and near the cavernous sinus which connect up with the external carotid branches, and these branches enlarge to a tremendous extent in an attempt to feed this communication. Recently I had a case which had been treated conservatively without benefit, and there is no reason why these cases should not be treated first by the conservative ligations as mentioned by the speaker. This little 11 year old fellow had had the common carotid ligated in the neck. After three months I ligated the carotid proximal to the ophthalmic artery intracranially, and there remained a tremendous bruit and a pronounced exophthalmos. At a third operation I opened the internal carotid artery in the neck and placed a muscle strip with a silver clip on the end of it, as an embolus, and then ligated the external carotid. It progressed upward to the fistula, and x-ray examinations showed the silver clip in the cavernous sinus. Before the external carotid was ligated, and before I had inserted the muscle embolus inside the internal carotid, after closing it temporarily with a tape, we could still hear the bruit, showing that the communication was being fed by the tremendously overdilated branches of the internal carotid through which the circulation had been reversed by their connections with the meningeal vessels, which are external carotid branches. This boy has stayed entirely well now for six months. His eyesight is normal. There is not the least pulsation, bruit or exophthalmos. Of course I do not think we should completely evaluate these cases until we have observed them for five years, because frequently the circulation will be cut down through these communications to such an extent that one may think one has effected a cure, but give them time, time for the collateral circulation to develop, and a great many of them will recur.

The Indispensable Amino Acids—If all ten of these are provided in suitable amounts, the body can form from them the remaining amino acids which enter into the composition of its proteins. The amino acids now called "indispensable" or "nutritionally essential" in the sense that they must be furnished through the nutriment, are arginine, histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan and valine.—Sherman, Henry C. *Chemistry of Food and Nutrition*, New York: Macmillan Company, 1941.

DELAY IN THE TREATMENT OF CANCER

CHARLES R. HARMS, M.D.

JULES A. PLAUT, M.D.

AND

ASHLEY W. OUGHTERSON, M.D.

NEW HAVEN, CONN.

Cancer ranks second only to cardiorenal disease in our mortality statistics. The attempt to reduce this appalling figure has been directed along two chief lines, namely the prevention and the cure of the disease. In order to accomplish either of these ends it is now generally recognized that both the medical profession and the public must be better informed regarding the cancer problem. Various national, state and local organizations have instituted educational programs better to accomplish this purpose. The need for such an educational program has been clearly recognized by many physicians for well over a century. While considerable progress has been made, we are nevertheless far short of the goal and the cancer death rate during the past century has been steadily increasing. The present study was undertaken in order better to evaluate the effectiveness of our present educational program.

It is generally recognized that the treatment of cancer by the methods which are now available must be early and adequate in order to be successful. The successful treatment of cancer may be divided into four steps, namely:

1. Early recognition of the signs and symptoms by the patient. He must at least be aware of the possibility of cancer in order that he may call on his physician for advice.

2. Early diagnosis by the physician, who must also be aware of the possibility and the steps that are necessary in order to make the diagnosis.

3. Prompt treatment, which requires the cooperation of both the patient and the physician.

4. Adequate treatment, which also requires the cooperation of the patient and specialized knowledge and technic by the doctor.

The present study is an attempt to determine the factors responsible for delay in the recognition, diagnosis and treatment of cancer. These factors cannot be adequately determined from a study of the usual clinical record, hence 158 successive cancer patients were interviewed as they were admitted to the New Haven Hospital or Tumor Clinic. Of these patients 153 were of either ward or dispensary status.

The definition of delay due either to the patient or to the physician must necessarily be arbitrary. It is also well known that the time required to recognize and diagnose a cancer which is visible on the exterior will be quite different from that on the interior of the body. However, it is not necessary to justify any arbitrary time chosen to define delay, since the facts may be so presented as to enable any one to draw his own conclusions. Furthermore, it is not our purpose

Dr. Plaut is National Cancer Council Fellow.

From the Tumor Registry of the Department of Surgery, Yale University School of Medicine.

This study was aided by grants from the Jane Coffin Childs Memorial Fund for Medical Research.

in this paper to make excuses for delay but rather to attempt to determine the steps which are needed in order to recognize, diagnose and treat cancer at a time when the disease is still localized and offers an opportunity for cure

Delay by the patient may be defined for purposes of discussion as having persistent symptoms for one

TABLE 1—*Distribution of Responsibility for Delay*

Type of Cancer	Total Number of Cases	Number in Which Patient Was Responsible	Number in Which Physician Responsible	Both Patient and Physician Responsible	Median Total Delay in Months

No delay	3				

* These percentages are based on a total of 155 cases

month or longer before consulting a physician. Delay by the physician may also be arbitrarily defined as waiting for any period longer than three weeks after the patient is first seen during which a diagnosis may be established or a consultation requested.

The distribution of the cancer by site may be seen in table 1. Three patients came immediately to the hospital for emergency treatment, 1 because of intestinal obstruction and 2 because of hemorrhage. The other 155 patients presented delay factors with responsibility distributed as follows: Eighty-five patients alone, or 54.8 per cent, were responsible for the delay, while 27 physicians, or 17.4 per cent, were responsible. Both the patient and the physician were responsible for the delay in 43 instances, or 27.8 per cent.

The patient was found to be either wholly or in part responsible for the delay in 128 instances, or 82.6 per cent. All but 7 of the 128 patient delays (121, or 94.5 per cent) were initial delays. The other 7 did not follow the physician's advice in spite of his efforts. The problem, therefore, appears to be mainly the initial delay or the interval between the onset of symptoms and the first visit to the doctor.

The cause for the delay by the patient is shown in table 2. The patients who thought their symptoms were "not serious enough" were capable of recognizing them but used poor judgment. Their information as to the possible serious nature of their symptoms was not enough to result in positive action. Those who were negligent knew the importance of their symptoms but allowed themselves to be sidetracked by other matters. The distinction between the negligent and the ignorant group is difficult to determine. Those patients were called "ignorant" who seemed to have a defect

in fact as well as in judgment and who displayed that defect generally and not limited to the problems of health.

Failure to attach sufficient importance to recognized signs and symptoms accounts for most of the delay. This is primarily an educational problem which is obviously not being met by present methods. The second most important factor defined as negligence may also in large part be corrected by proper education. The economic factor accounts for 10 per cent of the group. These patients recognized their symptoms for what they were, or at least as deserving medical care, but put off seeking attention because they did not know how to pay for it. It is noteworthy that fear of cancer plays a minor role.

The effectiveness of an educational program can best be judged by the content of knowledge possessed by the group as well as its effectiveness in producing appropriate action. The following general questions were asked in order to evaluate the information regarding cancer possessed by the group: How many patients with malignant tumors think of cancer as the cause of their complaints? Only 21, or 13 per cent, answered in the affirmative. Breast cancer was responsible for 13 of these. The median delay for patients who thought they had breast cancer was 3.25 months, while the median delay for all breast cancer was 6.5 months. This suggests that the delay could be halved if all patients were aware of the significance of their symptoms. It was also found that only 42, or 26 per cent, of the patients had read about cancer. Forty of the 42 readers had obtained their information from newspapers and popular magazines, while only 2 admitted reading public health pamphlets. Only 2, or 1.2 per cent, had ever heard a lecture on cancer, and both of these had been while attending National Hospital Day. Although the entire group seemed poorly informed regarding cancer, 80 per cent thought that cancer was curable and 91 per cent thought that treatment was urgent.

Patients may be expected to delay a short time after the onset of symptoms before consulting a physician. However, the median delay for the total group was 3.77 months. They were not aware of the serious

TABLE 2—*Cause for Delay*

Cause for Delay	Number of Patients	Per Cent
Total	158	100
Symptoms "not serious enough"	90	56.9

Christian science or other cult	1	0.6

* Limited to patients thought to be ignorant by observer

nature of their symptoms for part of this time. However, this group was aware of the seriousness of their symptoms for an average of 4.4 weeks before they consulted their physicians. Twenty-one per cent decided for themselves to consult their doctor, while the remainder were advised by their family (64 per cent) or friends (15 per cent).

Delay by the physician in making a diagnosis is also an important factor. It is appreciated that some of

this delay is unavoidable, however, every effort should be made to reduce this to a minimum. Table 1 shows that the physician alone was responsible for the delay in 27 instances (17.4 per cent) and that both the patient and the physician were responsible for delay in another 43 instances (27.8 per cent). The physician was therefore either totally or in part responsible for the delay in 45.2 per cent.

The information on which these data are based was obtained chiefly from the patient, and it is likely that

many of these patients did not cooperate by returning to their physicians for further study. For accurate information it would be necessary to interview both the patient and the physician.

The median time interval from the first visit to a physician until a definite diagnosis was made was four weeks. Thus, approximately one half of the patients had a definite diagnosis within a one month interval. When these patients were grouped according to location of tumor it was found that the tumors diagnosed within one month included larynx, skin, lip, prostate, uterus and breast. Those having a delay of more than one month included lung, stomach, esophagus, mouth, colon, rectum and bladder. The longest median delay was found in lung (15.45 weeks), stomach (18.75 weeks), bladder (13.74 weeks) and colon (16.35 weeks). While a portion of this delay was inherent in the greater difficulty of making a diagnosis, it was also obvious that the greater part was due to failure to carry out the more difficult and expensive diagnostic procedures until a diagnosis was fairly certain. General physical examinations were done by 62.6 per cent of the physicians, while local examinations directed at the complaint were done in 35.5 per cent. Three patients (1.9 per cent) received no examination. A history of some kind was taken on all patients, although it was impossible to determine the quality of the history. The delay by the physician usually was due to poor advice or incorrect diagnosis as a result of failure to carry out the indicated diagnostic procedures. The most common errors were failure to take a roentgenogram or do an endoscopic examination. The median overall delay between the onset of symptoms and proper treatment for all cases was 8.46 months.

COMMENT

It is generally acknowledged that the successful treatment of cancer by the methods now available is dependent on early diagnosis and treatment. How much may be accomplished by these methods in lowering the

present high mortality is unknown. Undoubtedly some cancers are so insidious in their onset that an early diagnosis and successful treatment are impossible. However, only the future can answer this question since so few patients receive treatment (8 per cent within two months) during the early stage of the disease as measured by symptoms. The medical profession has been discussing the need of public and professional education on the cancer problem for more than a century, and only recently has an attempt been made to put this into effect. The effectiveness of such an educational program can be measured only in terms of results.

The present study, which is based on 158 patients, is inadequate to give an accurate picture for the state. However, it does yield information as to the need of cancer education in the city of New Haven and particularly in the ward and dispensary groups.

Only 3 patients presented themselves for treatment within one month of the onset of symptoms, and these because of acute conditions rather than the presence of cancer. Ninety-two per cent of all patients required two months or longer and 84 per cent required three months or longer before adequate treatment was instituted. The median interval between the onset of symptoms and proper treatment was 8.46 months. These findings clearly indicate that there is unnecessary delay in obtaining proper treatment for cancer. Considering our knowledge of the growth and spread of cancer, good results in the total group cannot be expected under these circumstances.

The patient was responsible for the delay in more than three fourths of the instances. The patient was also responsible for the greater part of the time lost with a total median delay of 3.77 months. The physician was responsible for the delay in less than 25 per cent of the instances. The median time required by the physician to make a diagnosis was four weeks. Thus 50 per cent of all patients required more than four weeks to establish a diagnosis after first consulting their physician. It is apparent that the patient delay constitutes the major problem in the diagnosis and treatment of cancer. However, the physician also must assume a share of the responsibility.

The major cause for the patient delay is primarily lack of proper information on the cancer problem. A failure to recognize the serious nature of symptoms was responsible for 56.9 per cent of the patient delay, while expense, negligence and ignorance accounted for 10.1, 11.3 and 6.9 per cent respectively. Thus the failure of the educational program to furnish the patient with sufficient information may be held responsible for delay in at least 85 per cent of the cases.

Cancer education of this group of patients appears to be quite inadequate. Their information was obtained chiefly from newspapers, only 26 per cent had ever read about cancer, while only 1.2 per cent had ever seen a cancer pamphlet. Only 1.2 per cent had ever heard a lecture on cancer. It is apparent that more widespread and effective educational methods are needed if the public is to be made aware of cancer problems.

Delay on the part of the physician was found chiefly in cancer of the internal organs. The major part of this delay was due to the failure to request x-ray or endoscopic examination. The responsibility of the

physician cannot be fairly estimated in this study, since in most instances the physician was not interviewed and the information was obtained from the patient. The early investigation of cancer of the internal organs is a difficult problem because of the expense involved. Many of the early symptoms of cancer of the internal organs are difficult to distinguish from functional disorders, which constitute such a large proportion of the general practice of medicine. In order to evaluate this problem properly, studies should be carried on with the cooperation of physicians engaged in the general practice of medicine. This is also a problem which will grow in importance as patients present themselves for earlier diagnosis.

SUMMARY

1 Delay in the diagnosis and treatment of cancer is one of the most important factors in the failure to obtain better results by the methods of treatment now available.

2 The patient is responsible for the major part of this delay both in numbers and in the time consumed.

3 This delay by the patient is chiefly due to lack of information as to early signs and symptoms of cancer.

4 The education of the people on the cancer problem is a mutual responsibility of the public and the medical profession. This educational program is still inadequate and ineffective.

Clinical Notes, Suggestions and New Instruments

STREPTOCOCCIC MENINGITIS FOLLOWING CRANIO CEREBRAL TRAUMA

RECOVERY FOLLOWING THE USE OF SULFAPYRIDINE AND SULFADIAZINE

JOSEPH G. RILEY, M.D. AND RICHARD L. WAUGH, M.D.
BOSTON

The introduction of the sulfonamide drugs in 1935 by Domagk¹ has radically influenced the treatment of the bacterial meningitides. Symptomatic supportive treatment and an attitude of hopeful, purposeless expectancy have given way to positive specific therapy. The efficacy of the sulfonamides can be gaged by a review of the mortality statistics of the various types of meningitides, the lowered mortality rate and the increased incidence of survival of patients reflecting clearly the worth of chemotherapy.

The mortality of epidemic cerebrospinal meningitis in the period from 1926 to 1938 was estimated at 47 per cent.² In 1941 it was reported as 12 per cent in a large series of unselected sulfonamide treated patients.³ Similar reductions have taken place in the mortality rates of the other bacterial meningitides, notably of the streptococcic type.

Streptococcic meningitis prior to 1935 claimed a mortality of 95 to 97 per cent,⁴ despite heroic regimens of symptomatic treatment. However, in 1936, when Causse, Loiseau and Gissel-

brecht⁵ reported the first case of streptococcic meningitis with recovery following the use of azosulfamide, a new therapeutic era was inaugurated. Subsequently the literature began to see many reports of cases of streptococcic meningitis in which recovery occurred following the use of specific chemotherapy.⁶

A review of these published survivals following successful positive therapy with the sulfonamides reveals that the great majority have been secondary to otitis. There has been a scarcity of published reports of cases of post-traumatic streptococcic meningitis successfully treated with the sulfonamides. In addition, most of the recovered cases appearing in the literature, whether secondary to otitis or post-traumatic in nature are those in which sulfanilamide or azosulfamide has been used.⁷

Since later clinical investigation⁸ indicates that the newer sulfonamides sulfapyridine and especially sulfadiazine are effective against streptococcic meningitis, we believe that this report of a case of post-traumatic streptococcic meningitis treated successfully with sulfadiazine is of interest.

REPORT OF CASE

W. L., a man aged 33, an iron worker, entered the hospital Feb. 2, 1942 after he had fallen from a staging, landing on his face and outstretched hands. He had been unconscious for about ten minutes.

On admission he was conscious and rational. There were multiple abrasions and areas of ecchymosis on the right side of his face and forehead. There was no bleeding from the ears but the nares showed some crusted blood. Both wrists were swollen and painful with typical dinner fork deformities. The right elbow was swollen and painful with decided limitation of motion. The temperature was 37 C (98.6 F), the pulse rate 88 and the respiratory rate 22. The blood pressure was 120 systolic and 80 diastolic. Roentgenograms showed bilateral Colles' fractures, a simple fracture of the head of the right radius and a linear fracture involving the left frontal bone and extending laterally from the left frontal sinus.

Since there was no evidence of shock, both Colles' fractures were promptly reduced under intravenous pentothal sodium anesthesia.

The course for forty-eight hours after admission was uneventful. Soon thereafter, however, the patient became increasingly restless, irritable and drowsy. There was extreme rigidity of the neck and positive Kernig signs. His temperature rose to 41.2 C (106.2 F), with a pulse rate of 68. His respirations were deep and stertorous. The blood pressure was 200 systolic and 100 diastolic. A lumbar puncture at this time showed a spinal fluid pressure of 550 mm., with turbid fluid containing 15,000 polymorphonuclear cells per cubic millimeter. The spinal fluid protein was 85 mg., the chlorides 670 mg. per hundred cubic centimeters. The sugar was too low to be accurately determined by the ordinary tests. A stained smear of the

spinal fluid showed a gram positive diplococcus which morphologically resembled the pneumococcus

With the signs and symptoms indicative of meningeal infection, the administration of sulfapyridine was begun. Four Gm of sodium sulfapyridine was given intravenously followed by an additional 2 Gm in six hours. Subsequently, sulfapyridine was given by mouth in doses of 2 Gm every four hours for four doses.

At this time (twenty-four hours after onset of signs of meningeal infection) the culture of the spinal fluid was reported as showing a nonhemolytic streptococcus. The sulfapyridine was then discontinued and sulfadiazine was started in doses of 2 Gm every four hours. After three days the amount of this drug was reduced to 1 Gm every four hours. The patient was considerably improved, although the temperature remained at 38 C to 39 C (100.4 F to 102.2 F) and there was still definite rigidity of the neck and positive Kernig signs. Culture of the spinal fluid remained positive. Despite these findings, the patient was rational, oriented and was able to take nourishment and medication orally. The accompanying restlessness, irritability and severe headaches were alleviated greatly by lumbar drainage.

After twelve days of this medication, the patient showed pronounced general improvement and the drug was discontinued. At this time the spinal fluid was clear, the cell count was 110, the dynamics were normal and the culture was negative.

Within seventy-two hours after cessation of the drug the patient began to complain of severe headache and showed increasing restlessness. Sulfadiazine was begun in doses of 1 Gm every four hours. In twenty-four hours the headache and restlessness had disappeared and the temperature was normal. The drug was continued for eight more days. The patient remained rational and comfortable, with no complaints other than occasional slight headache and very slight rigidity of the neck. There was no recurrence of either the symptoms or the fever. A lumbar puncture done thirty-three days after the onset of the meningitis (ten days after final discontinuance of the drug) showed normal dynamics and clear spinal fluid with normal cell count, sugar, chlorides and total protein and negative culture. There were no psychic changes or neurologic sequelae demonstrable. The patient was discharged from the hospital as recovered on March 25, 1942.

COMMENT

In analyzing this case we believe that the following points are worthy of emphasis:

1. Despite the numerous reports of cases of streptococcal meningitis following otitis successfully treated with the sulfonamides, a review of the literature reveals a comparative rarity of cases following cerebral trauma which have been successfully treated by chemotherapy. To our knowledge this is one of the earliest cases treated with sulfadiazine with recovery.

2. The mortality of streptococcal meningitis, which in the presulfonamide era was almost 100 per cent, has been reduced materially through the introduction of chemotherapy. The minimal toxicity of the newer sulfonamides such as sulfadiazine should lead to a more obvious decline in the mortality rates of these infections.

3. The effectiveness of sulfadiazine as a therapeutic agent coupled with its low toxicity makes this the drug of choice in the treatment of streptococcal meningitis. In this case no single symptom which could be classified as due to toxicity of the drug was noted. There was no nausea or vomiting, no cutaneous eruption, no hematuria, no elevation of the nonprotein nitrogen and no decided change in the blood picture other than a mild secondary anemia, despite the administration of rather large doses for long periods.

Special Article

HANDBOOK OF NUTRITION XXI

NUTRITIVE REQUIREMENTS IN PREGNANCY AND LACTATION

J. HARRY EBBS, M.D.

TORONTO, ONT.

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed.

The ideal normal nutritional state for pregnancy would be one in which the maternal body was endowed with the proper nutritional elements before, during and after the pregnancy, to ensure the optimum needs of the fetus in its intrauterine development, to supply stores for its needs in early infancy, to ensure adequate nutrition for the normal physiologic requirements of the mother, and for the added requirements resulting from pregnancy and lactation. It is therefore not enough to discuss the question of diet for the expectant mother by simply saying that her needs are those of any healthy woman. While we have been accustomed to thinking of the fetus as parasitic and therefore obtaining its nutritional needs even at the expense of the maternal stores, perhaps we should consider more optimum development of the fetus by making all needs readily available. Gross nutritional deficiencies are seldom encountered in the population today, but, as our knowledge of nutrition increases, more and more evidence is presented that there are minor deficiencies which impair to varying degrees the health and efficiency of our population. Such minor or subclinical deficiencies, which in the average individual would take weeks or months to develop, could be exaggerated and hastened by the increased nutritional needs during pregnancy.

To serve as a basis for discussion of the nutritive factors needed during pregnancy and lactation, without considering special obstetric problems, such as vomiting, it might be well to use table 1, which is a reproduction of the standards set by the Food and Nutrition Board of the National Research Council and adopted by the Washington National Nutrition Conference in May 1941 and by the Council on Foods and Nutrition of the American Medical Association.

DIET DURING NORMAL PREGNANCY

In order to supply the food essentials in the recommended amounts it would be necessary to provide the following foods daily in approximately the amounts specified: milk, 40 ounces (2½ pints), cheese, 1 ounce, butter, 2 ounces, egg, 1 serving, meat, 1 serving (liver once a week), potato, 1 serving, yellow or green leafy vegetable, such as carrots, spinach, chard, string beans, or green peas, 1 serving, vegetable such as cabbage, turnip or tomato, 1 serving, orange juice, 3 ounces, or grapefruit juice, 4 ounces, or tomato juice, 7 ounces, other fruits, 1 serving, whole grain or enriched bread, 4 slices, whole grain or restored cereal, 1 serving. Extra calories necessary would be provided in the other foods.

From the Department of Pediatrics, University of Toronto Faculty of Medicine.

eaten in the daily diet according to the individual needs and taste. A supplement of fish liver oil or its equivalent should be prescribed to provide 400 to 800 units of vitamin D.

CALORIES

McCollum¹ states that during pregnancy there is a rise in basal metabolism which is 23 per cent higher at term than at the fourth month. The gain in weight, however, is only 14 per cent. The fetal tissues have a higher specific metabolism per unit of weight than maternal tissues. While there is increased metabolism toward the end of pregnancy, this is to some extent compensated by the necessary restriction of muscular activity during this period. The normal desirable weight gain in pregnancy according to some authorities is 20 to 25 pounds, spaced to gain 3, 10 and 10 pounds in the three trimesters.² The appetite is often diminished during the first trimester, and caloric requirements may be difficult to maintain. In the latter half of pregnancy the appetite may be increased.

FAT AND CARBOHYDRATE

Fats and carbohydrates supply the energy in the normal diet and are usually present in sufficient quantity. Their importance apart from being a source of calories, is in the absorption of vitamins by the fat

experience, in which it was found that the average birth weight of babies born to a group of mothers who were given extra food during the latter months of pregnancy was 7 pounds 7 ounces, compared with an average of 7 pounds 10 ounces in a group whose mothers were left on a poor diet which was much lower in total calories.³

PROTEIN

Metabolism studies as reported by several workers⁴ indicate the increased requirements for protein during pregnancy and lactation. The needs of the normal nonpregnant woman of about 1 Gm per kilogram of body weight must be increased to a total of from 90 to 125 Gm daily in order to provide for the growth of the fetus and the uterus.

The role of protein in kidney damage and its place in the cause and course of toxemia of pregnancy are still debatable.⁵ Protein is still restricted by many in the management of toxemia, and it is believed that clinical experience supports the view that toxemia is improved or prevented by protein restriction.

Williams⁶ says that a deficiency of protein may lead to nutritional edema and tends to anemia, poor muscle tone, lowered resistance to disease and poor milk supply.

Barker¹⁰ found protein poor diets in about 50 per cent of both clinic and private patients. A condition

TABLE 1—Recommended Daily Allowances of Dietary Essentials for Women

	Calories	Protein Gm	Calcium, Gm	Iron Mg	Vitamins				
					A I U	B ₁ Mg	C, Mg	Riboflavin, Mg	Nicotinic Acid Mg
Woman 55 kg nonpregnant	2 500	60	0.8	12	5 000	1.5	70	2.2	15
Pregnancy (latter half)	2 500	85	1.5	15	6 000	1.8	100	2.5	15
Lactation	3 000	100	2.0		8 000	2.3	150	3.0	23

(Formulated by the Food and Nutrition Board of the National Research Council 1941)

and the protein sparing action of carbohydrate. The ratio of carbohydrate and fat to protein and other so-called protective foods usually varies with the economic level of the family. The lower the income, the lower the intake of animal protein and vitamin containing foods.³ Obesity and excessive gain of weight during pregnancy can be controlled to a certain degree by the regulation of the intake of fat and carbohydrate.

Rucker⁴ feels that a carefully controlled diet will determine the weight of the baby. By keeping a low fluid, fat and carbohydrate intake and by increasing the protein, while keeping the total calories about 1,800 a day, he claims that the length of labor is shortened and that there is a minimum of prematurity. However, most observers feel that only gross curtailment of food intake can affect the size of the fetus. In such cases there is always the danger of some or many specific deficiencies. Garry and Stiven,⁵ in a review of the available data up to 1935, find that the weight of the newborn is not influenced by the maternal diet unless there are extreme deficiencies. This has been my

of edema, sallow pasty complexion and puffiness of the face cleared up when his patients were put on a high protein diet.

An increase in protein in the diet tends to increase the yield of breast milk, while a decrease lowers the quantity of milk secreted.

Coons and Blunt¹¹ found that, the greater the retention of nitrogen in the last months of pregnancy, the better the chance of successful lactation.

One half of the protein in the diet should come from meat, eggs and dairy products.

CALCIUM, PHOSPHORUS AND VITAMIN D

One of the most important elements of the diet during pregnancy and lactation is calcium. With this mineral one can also link phosphorus and vitamin D. A decrease in the serum calcium in the last months of pregnancy has been shown,¹² with a return to normal after the pregnancy has terminated. In successive pregnancies with only short periods between, the serum calcium has been shown to be even lower. Mendenhall and Drake¹³ have ascribed numerous symptoms and complaints to a lack of calcium during pregnancy. They cleared up such complaints as muscle soreness, spasms, numbness, tingling and neuritis by giving calcium and viosterol to these patients.

Swanson and Iob,¹⁴ in a chemical analysis of the fetus, have shown that the calcium and phosphorus retained in the last two lunar months is 65 and 64 per cent respectively of the total body content of the full term fetus. In order to supply these needs, a daily intake of 1.5 to 2.0 Gm. of calcium is necessary.¹⁵

The relationship between calcium, phosphorus and vitamin D has been the subject of much research. It seems clear that vitamin D is related to the utilization and retention of calcium and phosphorus in the body. Vitamin D requires an adequate supply of calcium and phosphorus in order to provide a retention. In rats vitamin D causes an increased retention of calcium and phosphorus in the offspring when the diet is adequate.¹⁶ In a review by Jeans and Stearns¹⁷ it is pointed out that some persons can retain calcium in ample amounts if the intake is from 1.6 to 2.5 Gm., even without added vitamin D, but in rapidly succeeding pregnancies and periods of lactation, unless vitamin D is given there may be poor retention of calcium and phosphorus regardless of the intake.

That the amount of calcium and vitamin D in the mother's diet affects the density of the infant's bones and the structure of the teeth has been observed.¹⁸ Evidence has been presented to show the relation of the maternal diet to the development of rickets in the offspring. Maxwell¹⁹ has reported fetal rickets. Mellanby²⁰ has stated that calcium and vitamin D are often deficient in the mother's diet and feels that this is one of the predisposing factors in the development

of rickets. Grant and Goettsch²¹ have shown a greater and earlier tendency to rickets in rats born of mothers on diets low in calcium, phosphorus and vitamin D.

Macy and her co-authors²² reported that the addition of cod liver oil and yeast to the diets of nursing mothers resulted in improved calcium assimilation and a greater feeling of well being.

The amount of vitamin D which is necessary for adult mineral metabolism is not definitely known and the amount suggested in table 1, of 400-800 units, is largely arbitrary. The administration of vitamin D in some form seems to be indicated.

In supplying the calcium in the food, the requirements for phosphorus are usually automatically supplied.

IRON

A great deal of interesting work has been published in the past few years which has given us a clearer understanding of the relation of the maternal diet to the development of anemia in the mother and the infant. Studies in the anemia of rats have done much to help in the understanding of anemia in the human infant. Parsons, Hickmans and Finch²³ showed that rats fed on an iron deficient diet can rear their litters, but the second generation fed on the same diet will have diminished reproductive ability, the young will not grow properly and they will show a pronounced anemia. The hemoglobin at birth is lower in the second litter of rats on an iron deficient diet.²⁴ Murphy and Bowes²⁵ found that anemia was twice as frequent among mothers using an inadequate diet as among those using an adequate diet. Once the anemia is established, whether the so-called physiologic anemia of pregnancy or an iron deficient anemia, it is then impossible to raise the level by diet, no matter how nourishing or how much iron is available. It is therefore necessary to provide iron in such cases. Both maternal anemia and anemia of infants can be prevented by prophylactic iron therapy. Labate,²⁶ in studying three groups of women on different diets, reported that iron increased the hemoglobin whether the diet was good or not.

Neale and Hawksley²⁷ give as the cause of anemia in the mother (1) transfer of maternal reserve to fetus, (2) poor diet, (3) rapidly repeated pregnancies and twin pregnancies and (4) gastric anacidity or hypacidity. The cause of anemia in the infant, according to Parsons and Hawksley,²⁸ is either a deficient ante-

natal storage of iron or a deficient postnatal supply, or both. A prime factor in this deficiency is the presence of anemia in the mother. Strauss²⁹ pointed out that anemia was present during the first year of life in babies born of anemic mothers although the hemoglobin was normal at birth. Mackay³⁰ showed that there was a lower level of hemoglobin in every month of the first six months of life in infants born of anemic mothers than in infants born of mothers without anemia.

The minimum requirement during pregnancy seems to be 15 mg., and according to Macy and Hunscher³¹ it may be 20 mg. daily. Corrigan and Strauss³² showed the value of supplementing the antepartum diet with medicinal iron. The results obtained in the blood of the mothers were equally striking in the blood of infants in similar studies by Gottlieb and Streat³³.

VITAMIN A

The daily requirement of vitamin A is as yet unknown, but, from various surveys and as a result of correlated dark adaptation tests, suggested requirements have been set forth. That these are far from being completely acceptable is seen when one considers the difficulties and discrepancies in the methods of measurement. The manifestation of vitamin A deficiency in any gross form is extremely rare. The incidence of minor or subclinical deficiencies is as yet unknown, but newer methods of detection may bring these to light in the near future. Again, the widespread distribution of vitamin A and its precursor carotene in our common foods suggests that it is probably not seriously deficient. However, pregnancy and lactation place extra demands on the normal physiologic processes of the female, and it is probably wise to aim at an optimum level of vitamin A and thus be within the margin of safety until our present knowledge of requirements is extended.

The part played by vitamin A in reproduction is uncertain. Mason³⁴ noted an increased rate of premature births and stillbirths in animals on vitamin A deficient diets. The young were not suckled as long and lived a shorter time than normal. On the other hand, Cannon³⁵ found that congenital anomalies were not induced in the young of rats with a lack of vitamin A in the diet. They did, however, show abnormalities of pregnancy and labor as well as a tendency to sterility.

Williams, Hark and Fralin,³⁶ in observing a group of pregnant women, found 62 per cent with a low vitamin A content in an analysis of their dietary records. Only 37.5 per cent of these women had poor dark adaptation. Hirst and Shoemaker³⁷ found no significant obstetric complications among the women with vitamin A deficiencies.

Ricketts³⁸ has described severe deficiency manifestations of vitamin A simulating toxemia of pregnancy. His report deals with 2 cases.

The role of vitamin A in the development of the fetus and therefore its importance in pregnancy is strongly suggested by the work of Wolbach and Howe³⁹. They have shown changes in the structure of the developing teeth in vitamin A deficient rats and guinea pigs. Mellanby⁴⁰ has shown defective teeth in rats born of mothers on a diet deficient in vitamin A and feels that vitamin A deficiency is responsible for absent or defective enamel and dentin.

While the newborn infant has very low stores of vitamin A,⁴¹ the colostrum and early human milk are rich in this vitamin. Human milk contains the same amount of carotene and vitamin A as cow's milk but at the beginning of lactation contains five to ten times more.

It seems safe in our present knowledge of vitamin A requirements to believe that the requirements during pregnancy and lactation will be met by diet and the same supplement which provides vitamin D, namely 4 to 6 Gm. of cod liver oil or its equivalent.

VITAMIN B COMPLEX

Cowgill⁴² has shown that the requirement of the average person for vitamin B₁ depends on the basal metabolism and the caloric intake. Since these are increased in pregnancy and lactation, the intake of vitamin B₁, or thiamine, must be increased. Polyneuritis can occur during pregnancy,⁴³ and signs of minor deficiencies of vitamin B₁ are not uncommon. We⁴⁴ have been impressed by the changes which occurred when the intake of vitamin B₁ was doubled or trebled in women attending the antepartum clinic who had been on poor diets. Many of the minor aches and pains and numerous complaints disappeared. The mental attitude of many of these patients changed from one of apathy and discontent to one of interest in the outcome of their pregnancy. Williams and his co-workers⁴ in a nutrition study of pregnant women found practically one third of their patients on an inadequate intake of vitamin B₁, according to the Cowgill standard. Thirty per cent of those with an inadequate intake had moderate to pronounced nausea and vomiting compared with only 10 per cent of those with an adequate intake. Fatigue, cramps, paresthesias and dyspnea were also found more frequently in those with a low vitamin B₁ intake. Strauss and McDonald⁴⁶ point out that such evidences of polyneuritis should be treated with vitamin B complex.

The need of the lactating woman for vitamin B₁ is obviously higher than for the normal nonlactating woman. Cowgill⁴⁷ sets this at 15 or 20 units per hundred calories, which would be 500 to 700 units daily. The amount of vitamin B₁ in the milk depends to some extent on the amount in the mother's diet.⁴⁸ There is practically no storage of this vitamin in the body. The stimulating action of B₁ on the secretion of milk has been observed.

Riboflavin, or vitamin B₂ (G), is associated with oxidation processes of the cell. With the increased metabolism during pregnancy, the requirement of this vitamin is probably increased. Forms of keratitis have been described as evidence of deficiency of this vitamin.⁴⁹ The condition described by Sebrell and Butler⁵⁰ as a result of deficiency of riboflavin has been observed in 1 patient in our own clinic.

Riboflavin is found in milk, egg white, liver and leafy vegetables in such proportions that most diets should contain a sufficient amount.

Nicotinic acid and vitamin B₆ have not been demonstrated as having any particular significance during pregnancy, except that the requirement is probably increased in proportion to those of the other vitamins.

If the diet contains an adequate amount of whole grain products, milk, meat, egg and vegetable, the components of the vitamin B complex will be supplied in sufficient amounts.

VITAMIN C

With the perfection of methods for determining vitamin C in the body, the approximate needs have been fairly clearly determined for the average woman during pregnancy and lactation. Snelling and Jackson⁵¹ in this clinic found a slight fall in the ascorbic acid level of the blood plasma toward the end of pregnancy. This and a further drop during and after labor might be explained by the decreased intake at this time and by increased needs of the fetus.

Being water soluble, vitamin C is not retained in the body and therefore the level in the blood is directly affected by the amount in the diet.⁵²

The average plasma vitamin C of two groups of women measured during pregnancy is shown in table 2. Both groups were on poor diets when the blood was first examined. One group was then given one orange and 4½ ounces of canned tomatoes daily until the end of pregnancy. It will be noted that the average level of ascorbic acid in this group was higher in the eighth month and at term than in the other group. The parasitic nature of the fetus is demonstrated by the average level of vitamin C in the cord blood, which is higher than the level in the maternal blood at this time. Even when the maternal blood was practically depleted of ascorbic acid, the cord blood would contain appreciable though below normal amounts. The average levels in table 2 are lower than the desired level during pregnancy.

Sellig and King⁵³ have shown that the amount of vitamin C in the breast milk is dependent on the dietary intake of the mother. Totally breast fed babies are well supplied with vitamin C if the vitamin C content of breast milk is more than 4 mg. per hundred cubic centimeters. Mothers on low vitamin C diets can secrete enough vitamin C in the breast milk to give levels in the plasma of the infant which are higher than their own. While cases of scurvy in breast fed infants have been known, it is an extremely rare occurrence. Of 20 consecutive babies with scurvy admitted to the Hospital for Sick Children, Toronto, all were bottle fed.

It seems clear that the vitamin C intake during pregnancy and lactation should be increased above the amount usually required. Particular attention should be paid to the intake during the latter weeks of pregnancy, during lactation and during periods of vomiting or other dietary restriction. The diet should contain liberal amounts of orange, grapefruit or tomato juice as well as other fruits and vegetables.

VITAMIN E (ALPHA-TOCOPHEROL)

The need for vitamin E in normal pregnancy has been suggested recently. Its widespread distribution in foodstuffs makes it unlikely that any serious deficiency can occur. Reports of Vogt-Möller⁵⁴, Currie Shute,⁵⁵ Collins⁵⁶ and Watson⁵⁷ on the use of wheat germ oil in habitual abortion have been very encouraging.

TABLE 2—Plasma Vitamin C During Pregnancy

Group	8th to 6th Month	5th Month	Term	Cord Blood	Mother's Blood
	Mg. per 100 Cc.	Mg. per 100 Cc.	Mg. per 100 Cc.	Mg. per 100 Cc.	6 Week After Delivery
Diet poor in vitamin C	0.47	0.40	0.47	1.0	0.1
Improved diet added orange and tomato	0.46	0.61	0.7	1.4	0.5

Further reports continue to appear. Richman⁵⁸ summarizes the recent reports by suggesting that there is at least presumptive evidence that it is needed for normal pregnancy in women.

VITAMIN K

Evidence has been brought forward practically to establish the usefulness of vitamin K.⁵⁹ The administration of this substance to the mother just before the onset of labor or during this during labor has a definite effect on the prothrombin time of the infant.⁶⁰ A reduction in the incidence of hemorrhagic disease in the newborn period has been shown when mothers have been treated, and the use of this substance also seems to be indicated in the treatment of cases of hemorrhagic disease of the newborn.⁶¹

RELATION OF NUTRITION TO TEETH

Studies of the incidence and control of dental caries in the pregnant woman indicate that diet is a factor. There appears to be some truth in the old saying "For every child a tooth," and the observation has been commonly made that dental decay is increased during pregnancy.

The teeth, while requiring relatively little mineral salts in comparison to the skeleton are nevertheless dependent on maternal supplies for their normal development. Deficiencies in the maternal stores of essential food elements, such as minerals and vitamins, will probably be reflected in the structure of the teeth of the infant. Toverud⁶³ has found defects in the teeth under such conditions, and Mellanby⁶⁴ feels that deficiencies in antepartum diet are an important factor in dental caries appearing in the child.

In observations on three groups of patients in an antepartum clinic Daro⁶⁵ found a poorer condition of the teeth and gums in those who were on inadequate diets compared to those who were eating plenty of milk, raw fruits and vegetables. He points out the importance of deficiencies which might occur as the result of vomiting early in pregnancy.

Howe⁶⁶ makes a strong point "The dentist may and should indicate to the medical practitioner that the teeth are calcifying and the bones which carry the teeth are undergoing ossification during fetal life, and it is his duty to see that the normal processes of growth and development here go on uninterrupted. It is recognized that these processes are influenced more strongly by nutritional states than by any other factor."

While there are undoubtedly other factors in the production of dental caries, it seems reasonable that the period of development of the teeth is a most important one and the mother should be provided with the optimum requirements.

NUTRITION A FACTOR IN PREGNANCY

Is nutrition a factor of importance in the management of pregnancy? This question could be answered by general statements covering the knowledge that improved nutrition improves the general health and thus results in healthier mothers. Common sense and practical experience suggest the importance of proper food for the expectant mother. Poverty goes hand in hand with poor diets, but not all people with adequate incomes provide proper diets. Ignorance, illness and other circumstances also interfere with proper dietary habits.

The incidence of successful pregnancies is conceded to be better in those of good or moderate means in comparison to those who are on low income. A recent communication by Baird and Wiper⁶⁷ from Aberdeen makes such a comparison. In private specialist practice the rate for stillbirths and neonatal deaths was 12 per thousand; in hospital practice it was 54.5 per thousand and in the homes it was 78.5 per thousand live births. While there are several probable factors entering the outcome of these three classes of pregnant women, such as economic, nursing and medical, the authors say:

There is thus a large wastage of child life associated

with childbirth in Scotland, intimately connected with unfavorable economic conditions and malnutrition and fatigue in the mother."

Ross and his associates⁶⁸ reported that, in two groups of pregnant women, one group on a poor diet and another group on a well balanced diet, the incidence of toxemia and the levels of hemoglobin and serum protein were not significantly different. Church, Foster and Asher⁶⁹ showed that the diet of the mother was a factor in the survival of the offspring from the risks of infection.

In a recent study in this clinic⁷⁰ a group of pregnant women found to have very poor diets were divided into two groups. One group of 120 women on poor diets and with low incomes were followed during the last half of pregnancy as controls for 90 women on equally poor diets and low incomes who were supplied with milk, eggs, cheese, oranges, canned tomatoes, wheat germ and vitamin D capsules and who were instructed in the type of diet necessary for pregnancy. The observations made throughout pregnancy, during convalescence and on the baby showed a striking difference. The incidence of miscarriages, premature births and stillbirths, the number of infections in the mother and her general condition, both mental and physical, were much better in those who received the extra food. Changes in the blood of the mothers given extra food gave evidence that they were in a better condition during the stress of pregnancy. The general condition of the babies born of mothers who received the extra food was much better than the condition of those born of mothers who were left on their poor diets. The incidence of illness among the babies was much greater in the poor diet group.

While it is well recognized that there are many factors in the successful outcome of pregnancy, it seems reasonable that proper nutrition will ensure a more optimum general condition of the mother which will possibly prevent or at least minimize the complications that occur in pregnancy. The tired, depressed and physically poor women in this study, with a past history of a high percentage of complications, were poor obstetric risks. But even in four or five months of proper feeding this condition was greatly improved and the outcome of pregnancy was not only better than with those who were left on their poor diet but resulted in a lower rate of complications than they had experienced in previous pregnancies. This series is small and should be extended in women equally poor.

A much larger experiment was conducted in Great Britain,⁷¹ and, while the results were obtained in several districts and the experiment was not confined to one hospital, the series is so large and the results are so striking that they have some significance. Milk and egg products containing added vitamins A and D and another food rich in vitamin B were supplied during the last three months of pregnancy to needy mothers in the special areas of England and South Wales. The maternal death rate in 10,384 obstetric cases in which these foods were supplied was 1.66 per thousand total births as against a rate of 6.15 among 18,854 other cases in the same districts during the same period. There

was only one death from sepsis in the assisted group, as against forty-five in the nonassisted group. The number of stillbirths and neonatal deaths was 43 per cent less in the experimental group than in the nonassisted category.

SUMMARY

From the evidence presented it is apparent that the pregnant and lactating woman requires more calories, minerals, vitamins and protein than the nonpregnant woman. As shown by McCance and his associates⁷² the intake of these elements is influenced by the economic level in that "a rise in spending power led to an increased consumption of milk, fruit, vegetables and meat and a decreased consumption of bread and total cereals." They found the women on the better diets to be taller and less anemic.

The management of the nutritional needs of the expectant mother requires more care in the selection of a daily diet than does that of a normal nonpregnant woman. The increased requirements for protein, minerals and vitamins, if they are to be met by the food consumed, necessitate some instruction in most cases. This instruction can be given by the physician or by the dietitian in the clinic. Simple directions stressing the importance of eating the foods which supply the greatest amounts of the protective food elements are usually sufficient. The importance of milk, citrus fruits, green and yellow vegetables and whole grain bread and cereal are obvious. Apart from vitamin D, the requirements for the other food elements can be met by the food, provided the income is adequate.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
HOWARD A. CARTER, Secretary

VIBRAPHONE NOT ACCEPTABLE

Manufacturer: European Vibraphone Company, 120 Wigmore Street, London, W. 1. American Representatives, European Vibraphone Company, Inc., 4687 Hollywood Boulevard, Los Angeles.

The following description of the Vibraphone has been taken from the advertising used to promote the device:

"The Vibraphone is a tiny hollow instrument made of pure silver. A minute silver shell, within which is a vibration chamber, acts as a receiver of sound. It fits snugly into your ear. The tube of the instrument going into the opening of your ear until the ball settles comfortably into position. The shell, or vibration chamber rests in the curve of the outer ear. There are no wires, no batteries, nothing electric and there are no head bands, no trumpets, nothing to fit behind the ear, or to carry in the pocket or handbag."

In the firm's advertising is the following description of how the Vibraphone will aid the deafened person to hear:

"This principle is a valuable development of science. When sounds enter the Vibraphone a strong vibration is set up which transmits the sound impulses to the inner ear. With daily use, the affected ear accustoms itself to this helpful stimulation, and normal sounds may be heard with natural clarity in many cases."

The remarkable quality of these sound waves from the Vibraphone lies in the fact that they tend to set up vibrations in affected ears which normally have lessened power to transmit sound to the brain. Ears which are too sluggish, ears which have become out of order, and partially deaf by reason of causes already mentioned, tend to liven up under the continuous 'massage' of this amplified and concentrated sound from the Vibraphone. Hearing functions gradually tend to waken into

activity and your ear begins to live once more. Improved hearing is evidence of this.

"The progress of the improvements is more evidence still. Time will tell how perfect your hearing may become. The fact that your hearing is improved shows that your deafness may be bettered. Your confidence is justified. Your patience is rewarded."

The theory of gradually massaging the organs back to sensitivity by means of vibration has been exploited in other instances, and in no case has any critical evidence been submitted to substantiate it. The manufacturer of the Vibraphone asks the purchaser to withhold judgment of the aid until it has been used several weeks.

According to a statement, 'Your Deposit is Insured' in the promotional material, 'said European Vibraphone Company, Inc., warrants in its customers' contract to refund to the purchaser of its Vibraphone products the purchase price thereof less service charge of Six and no/100 Dollars (\$6.00) per pair or Three and no/100 Dollars (\$3.00) on a single Vibraphone if such product be found not satisfactory during the thirty (30) day trial period offered.' This financial arrangement seems to be very advantageous to the firm. Even though the customer has derived no benefit from the device and returns it he pays enough for the privilege of trying it. The manufacturer thus collects the 'service charge' and also receives the instrument, which he may resell.

It is not known whether the Vibraphone now promoted by the European Vibraphone Company and the Vibraphone referred to in the following paragraph are one and the same instrument but the claims made for the two instruments are identical and photographs of the devices show them to be very similar in appearance.

According to the article 'Deafness Cure Quackery and Pseudo-Medicine' by Dr. Arthur J. Cramp, former director of the Bureau of Investigation of the American Medical Association (*Hygeia* 4:21 [Jan.] 1926), the Vibraphone is an offspring of the "Radium Ear" or 'Audiophone' device promoted by one Charles Fensky. The Fensky device was a similarly shaped instrument which was 'improved' by the addition of a 'vibrator.' A St. Louis firm, the Vibraphone Company, took over promotion of the instrument.

The Better Business Bureau sent out a report on the Vibraphone in 1929 in which the results of an investigation made by the bureau were given. Several hundred letters were written to persons said by the manufacturer to be satisfied users of the instrument. By far the majority of the replies indicated that the device had been of no value as an aid to hearing. Many said that they could not wear it because it was so uncomfortable.

No evidence that this device, when tried under controlled conditions, would amplify sound and improve the hearing of a deafened person was made available. The Council voted not to include the Vibraphone in its list of accepted devices.

ALLERGEN-PROOF ENCASINGS ACCEPTABLE

Manufacturer: Allergen Proof Encasings Inc., 4060 Superior Avenue, Cleveland.

The Allergen-Proof Encasings were declared acceptable for inclusion in the Council's list of accepted devices in the *JOURNAL* of March 20, 1937, page 972. Designed to protect persons allergic to dust, feathers, cottonseed or kapok, the covers (fitted for various sized mattresses, pillows and box springs) were made of a rubber fabric composition treated by a process which increased the resistance of rubber to oxidation.

Because of priority restrictions the manufacturer is now unable to obtain a supply of the original fabric. A substitute has been found by the firm. This material is a cotton fabric impregnated with paraffin. According to the Council tests the material stands washing and ironing as claimed by the firm. It was tested against the effects of dilute acids, alkalis and soap. It stands up fairly well but is not as satisfactory as the original material. The Council believes it to be as good as can be obtained at the present time and that it will give satisfactory service if the manufacturers' directions are followed.

The Council voted to retain the Allergen Proof Encasings on its list of accepted devices.

POSTOPERATIVE NITROGEN LOSS

Much of the tremendous advance in surgery in the past decade or more has been achieved because of the recognition of various biochemical deficiencies and their correction by appropriate replacement therapy. Loss of water, loss of electrolyte, loss of plasma have all been studied and now are corrected rapidly and effectively by the parenteral route. Indeed with the purification of vitamins many of them can also be administered parenterally and replacement therapy carried out along with the intravenous injection of saline solution, dextrose and plasma.

Nitrogen loss after operation has been largely overlooked even though such loss, unless replaced immediately, means depletion of tissue protein. More important the loss leads to hypoproteinemia, which if severe, produces many serious clinical manifestations. Especially significant therefore, are the recent studies of Brunschwig and his co-workers¹ at the University of Chicago. They observed the nitrogen loss by 41 patients who were operated on for various reasons; the results were given in three groups and averaged 25, 51 and 89 Gm daily. The greatest loss was by a patient who had had a gastric resection and who, during ten days after operation was unable to take food and lost 175 Gm of nitrogen. This figure represented his negative balance and corresponds to 1100 Gm of protein, which actually means 5,500 Gm of tissue protein. In other words, this patient lost, during his first ten postoperative days over 12 pounds of muscle tissue or its equivalent. The significance of this loss, however, lies not in the loss of muscle tissue, for after all voluntary muscle is not needed for an immobile patient at rest in bed. The important point to emphasize is that all protein tissues of the body are affected even though in varying degrees. Of these, plasma protein is of primary importance and postoperative hypoproteinemia has in fact been amply observed

by many surgeons, of these perhaps one of the earliest was that of Jones and Eaton.² Doubtless with further study other manifestations of this excessive loss of nitrogen will become known. For example, depletion of liver protein provokes or at least aggravates the possibility of hepatic insufficiency, particularly when disease of the liver is present or is developing. Significant too, as indicating a deficiency are the observations of Farr and his co-workers,³ who found a fall in the amino acid nitrogen of the plasma during general anesthesia, which proceeded to an even lower level after operation.

Other observations⁴ on the tremendous loss of nitrogen following trauma, burns and operations amply justify the implications which flow from the Billings Hospital study. For example, it was obviously impossible to correct this loss by the usual methods of therapy. Oral alimentation helped, but after abdominal operations eating is often contraindicated and in many instances was in any event limited because of anorexia. Intravenous dextrose spared protein breakdown and reduced nitrogen loss to a considerable extent but could do so only by supplying adequate calories, unfortunately the loss of nitrogen is only in part due to this factor. Plasma transfusions are useful but, for the small amount of protein food introduced, are expensive and inconvenient. Actually the loss was corrected by supplying nitrogen in the form of the building stones of protein (amino acids and polypeptides), which were prepared from a digest of casein and pork pancreas and injected intravenously, thus achieving a physiologic short cut over the natural method by sparing the need for digestion and absorption in the gastrointestinal tract. In many of the cases a sufficient dose was injected so that positive nitrogen balance was achieved. One patient with an obstruction of the sigmoid took nothing by mouth yet 508 Gm of nitrogen was retained during ten days or, in terms of muscle tissue, a gram of nearly 3½ pounds. In others the magnitude of the protein depletion was significantly lowered. The importance of dextrose in the metabolism of amino acids was shown by the failure to achieve nitrogen balance with the protein digest alone. Other observers also have used intravenous injections of hydrolyzed protein and have confirmed these results.

It may be pertinent now to emphasize the importance of covering postoperative loss of nitrogen in this way as a routine. Dextrose is widely given after operation to supply calories, yet nonessential tissue fat can easily substitute in part for it, nitrogen loss on the other hand, must be met by exogenous sources unless

depletion of essential body and plasma protein is to be avoided. In this sense consideration of nitrogen loss after operation deserves more serious consideration than caloric needs. This is particularly true in view of the ease and simplicity with which the loss can now be covered. The intravenous injection of protein nourishment with protein digests is certainly now as convenient as the administration of dextrose and saline solution, this contrasts strikingly with the inconvenience and expense of giving large transfusions of plasma as a source of protein food. Many hitherto unexplained postoperative complications are undoubtedly due to excessive nitrogen loss and will be avoided by extensive use of this new method of parenteral protein alimentation.

ADVANCES IN MUSCLE PHYSIOLOGY

One of the unsolved problems of muscle contraction has been the bridging of the gap between the chemistry of the energy producing reactions involved and the physical processes of shortening and lengthening of the muscle fiber. The detailed chemical transformations of the energy producing mechanisms and their inter-relationships have been elucidated during the course of the past two decades, and the energy changes involved have been measured quantitatively. The phosphorylation cycles whereby energy is transferred from carbohydrate breakdown to the muscle fiber have been worked out in detail¹. Physical studies, chiefly with the aid of x-ray analysis, have yielded a rather complete picture of the alterations which occur in the muscle fiber when subjected to varying amounts of tension *in vitro*. Muscle contractibility is essentially a molecular contractility of the protein (myosin) chains². However, the means by which the energy produced by the chemical processes is linked or transferred to the muscle fiber so that the latter may actively shorten and relax has been entirely a matter of speculation. Now experiments have been presented which yield data for partial solution of this problem. The story promises to be one of the great contributions of biochemistry to modern medicine.

This important contribution to the integration of the chemical and the mechanical features of muscle contraction has come from a laboratory in the Soviet Union. Englehardt and Ljubimova³ in 1939 discovered that the enzyme adenylypyrophosphatase is either myosin itself or some closely associated protein. This observation has been confirmed and extended in three other laboratories⁴. Its significance is twofold. 1 The breakdown of adenylypyrophosphate is of the various

processes occurring in the metabolism of muscle the nearest in time to the contraction of the muscle fibrils. 2 The quantitatively largest part of the breakdown of adenylypyrophosphate probably occurs by splitting off of free phosphate under the influence of the enzyme adenylypyrophosphate, now suggested to be identical with myosin.

The acceptance of the foregoing suggestion rests in part on the failure of all attempts to separate the enzyme adenylypyrophosphatase from the protein myosin. In addition, important supporting evidence comes from detailed observations now available on the physical alterations which occur in the protein myosin as an accompaniment to the combination of myosin with adenylypyrophosphate (enzyme-substrate combination) and the subsequent enzyme action (splitting of inorganic phosphate from the adenylypyrophosphate). Englehardt and his colleagues⁵ treated partially dried myosin fibers, still retaining some adenylypyrophosphatase activity, with a variety of substances. Only adenylypyrophosphate showed any effect and this was to produce an increase in extensibility of the fibers. Needham and his collaborators⁶ have demonstrated that adenylypyrophosphate has a direct influence on the relative optical anisotropy and on the shape of myosin particles. The physical changes which take place in the myosin fiber, and the capacity of the latter to catalyze the breakdown of adenylytriphosphate to adenylydiphosphate, are catalyzed by the calcium ion. The importance of the latter ion in maintaining the response of isolated muscle to stimulation has been known from the earliest studies in muscle physiology.

From the available data, a number of interesting concepts are suggested. The essential feature of excitation and contraction in muscle may be, as Bailey⁷ has proposed, the liberation of the calcium ion in the vicinity of the adenylypyrophosphate grouping which can thus, by the almost instantaneous catalysis of adenylypyrophosphate breakdown, make available a huge amount of energy. The contraction of the myosin fiber would accompany the combination of the adenylypyrophosphate with the enzyme myosin, as indicated not only by the far reaching changes in myosin observed optically and accompanying the enzyme-substrate combination but also by the enzyme action itself. With this concept the energy producing phosphorylation cycles become coupled with the physical changes in the myosin fiber observable during shortening and lengthening. Indeed, myosin now becomes a "contractile enzyme". One may view the muscle of the body, comprising approximately 25 per cent of the total body weight, as a collection of enzymes.

PREDETERMINATION OF SEX

From earliest antiquity scientists, philosophers and magicians have speculated as to why the offspring is male or female. Biologists have attempted to discover means by which the desired sex could be produced at will. Only with the advent of this century, however, has any scientific foundation for this eventuality been developed. Among the most important early observations was the demonstration that sex among higher animals is determined by genes. Thereafter it became clear that sex is determined in human beings (as in some lower animals) at the time of the fertilization of the egg. Subsequent activity, whether dietary or metabolic, does not change the sex of the child. Furthermore, to the astonishment and possibly distress of some of those with preconceived ideas, human sex is determined by the presence or absence of a particular gene or set of genes of the father rather than by the mother. No longer may the wife be blamed for failure to produce the wished for son!

With the ground work thus laid for scientific approach to predetermination of sex the subject is emerging from folklore into science. In predetermination of sex of insects and possibly mammals extensive advances have been made. Gowen and Nelson¹ say that "many problems of sex differentiation and distribution are, of course, left, but, in the sense of establishing means for sex control through specific agencies under man's guidance, the problem of the predetermination of sex may be said to be solved."

The work on which much of this astounding assertion is based has been done by many investigators and is based largely on observations on *Drosophila melanogaster*—a fly which has served geneticists as the perfect laboratory animal. As Gowen and Nelson point out, the unbalanced condition of one or more chromosome pairs in one sex furnishes the mechanism whereby the distribution of sex in a population is random with a mean approximating an equality for the two sexes. The occurrence of sex linked lethals (a type of gene which results in death and which occurs spontaneously or can be produced by x-rays and other means) gave students of inheritance the first positive means of controlling the sex of the progeny of a set of parents. By refinements of technique involving the introduction of one or more lethal genes in each of the sex chromosomes with prevention of crossing over (i.e. prevention of exchange of genes between homologous chromosomes) it was shown that sex control could be made practically perfect with no males to 100 per cent adult females. As the final step in the voluntary control of sex determination, Gowen and Nelson presented an example of genotypic control (control of genetic type) which led to progeny of 100 per cent males. In crosses intended for cer-

tain other genetic studies a pair mating of *Drosophila melanogaster* was observed which produced 136 males and no females. The male progeny of this cross were able to transmit the male producing characteristic to certain of their daughters without regard to the characteristics of the mates to which they were bred. In something over five hundred matings covering a period of eight generations from the original parents, failures in finding the expected male producing genotype did not occur. The daughters with the genotype for all male progeny produced all male offspring without regard to the mates with which they were bred. The males, however, gave no phenotypic expression (i.e. no visible expression) of this inheritance. The male producing genotype is thus without effect on the adult males which carry it. The inheritance is therefore sex limited in its action, affecting only the females which have it, acting as a dominant. This, Gowen and Nelson believe, is the final proof that genotypes may be established which can be genetically controlled for the most divergent sex ratios possible—100 per cent female in one progeny and 100 per cent male in the other.

This startling discovery does not of course signify that it will be possible in the foreseeable future for parents to choose in advance the sex of their children. But it does establish for the first time on a scientific basis the fact that this can be done experimentally among lower animals by man devised methods.

Current Comment

PORTS OF ENTRY OF POLIOMYELITIS

Despite much clinical and experimental work, the usual port of entry of poliomyelitis virus has not been precisely determined. The accumulated evidence suggests that the olfactory system is not as a rule primarily involved and that invasion generally occurs through the alimentary tract. The part of the canal most vulnerable to virus penetration however, is still undetermined. New experimental evidence developed by Faber and his colleagues¹ suggests that the oropharyngeal surfaces are the commonest port of entry. Using cynomolgus monkeys and Sabín's "Per" strain of the virus, the Stanford clinicians were unable to infect monkeys by oral administration of massive doses enclosed in capsules covered with a digestible fat. The same monkeys resisted infection by a high enema consisting of 5 cc of a 20 per cent virus suspension. Some months later, after zinc sulfate olfactory blockade, the mouth of one of these monkeys was sprayed on three successive days with 5 cc of a 10 per cent cord suspension supernatant. Five days after the first spraying, fever, slight weakness of the arms and mild head tremors were noted, the usual symptoms of incipient poliomyelitis. At this stage the animal was etherized, exsanguinated and perfused with isotonic solution of sodium chloride and 10 per cent solution of formaldehyde. Careful microscopic study was made of the

¹ Faber, H. K. and Silberberg, R. J. *Science* 96: 475 (Nov. 20) 1942.

central and peripheral nervous system. Typical lesions of poliomyelitis consisting of small cell infiltrations, chromatolysis, neuronal necrosis and neuronophagia were noted in several ganglions, the heaviest lesions being in both gasserian and in both nodose (tenth nerve) ganglions. Moderately severe lesions were noted in both petrosal (ninth nerve) ganglions, in three of six cervical sympathetic and in two of ten upper thoracic ganglions. Small lesions, few in number, were found in one geniculate (seventh nerve) ganglion, in one lumbar sympathetic ganglion and in two of fourteen thoracic spinal ganglions. In the medulla a few typical parenchymal and perivascular infiltrations were noted, but without definite cell necrosis. Lesions were not found elsewhere in the brain stem, in the olfactory bulbs, the lower thoracic sympathetics, the celiac and cervical spinal or lumbar spinal ganglions or in the spinal cord. Assuming that the few slight lesions in one lumbar sympathetic ganglion resulted from an inapparent infection from the earlier virus enema, Faber concludes that the lesions found in this monkey could all be explained on the assumption of a nerve borne infection entering through the oropharyngeal surfaces. He believes this entrance was "mainly through the fibers of the fifth, ninth and tenth nerves (probably including the gustatory) and to a lesser extent through the sympathetics." Thus the mouth and the pharynx appear to be more vulnerable to penetration by this virus than the lower portions of the alimentary tract.

TREND OF INFANT MORTALITY

No other country approaching the United States in race complexity and climatic diversity has as low a rate of infant mortality, according to a recent special report of the Bureau of the Census.¹ "In 1940," says this report, "the United States, with a rate of 47.0 per thousand live births, occupied the seventh position in the international rank order of infant death rates."

The lowest death rates were recorded for Norway, Sweden, Netherlands, Australia and New Zealand, the rates for these countries ranging between 37 and 39 infant deaths per thousand live births. Switzerland, with a rate of 46 per thousand live births in 1940, was the other country with a lower infant mortality rate than the United States.

The report also notes "that the 1940 infant death rate for Germany was 65 per thousand live births and for Italy 104, while the latest available rate (1936-1938) for Japan was 112 per thousand live births." Germany has had the most comprehensive system of compulsory sickness insurance for the longest period of any nation. The Nazis have succeeded in increasing the birth rate from 14.7 in 1933 to 20.4 in 1940 but the opinion is expressed that "this success was due to increased reemployment of the population and not to any elaborate 'population blueprints'." This opinion seems to be confirmed by the increase in the United States from 16.6 in 1933 to 18.9 in 1941. The Monthly Vital Statistics Bulletin, Dec. 8, 1942, brings the information concerning the birth rate since that "for the first ten months of 1942 the provisional rate is 20.5 with indications that the rate is still rising."

The most important period of infancy, from the standpoint of mortality, is at birth. In 1940 13.9 per thousand infants born alive died during the first twenty-four hours after birth.

After the first day of life the chances of survival of the newborn infant improve considerably. The death rate for the 1 day old infant is 3.5 per thousand live births as compared with that of 13.9 per thousand live births for infants under 1 day of age.

However when infant mortality statistics are correlated with the births attended by physicians and by midwives holding total births constant, it is found that infant deaths are negatively associated with births attended by physicians and positively correlated with births attended by midwives. In each case the partial correlation coefficient is highly significant but these coefficients cannot be interpreted to mean that there is a causal relationship between infant deaths and births attended by physicians or by midwives. The correlation coefficients merely indicate that there is a highly significant association existing between these factors and that infant mortality is lower in states with a large proportion of births attended by physicians and higher in states with a large proportion of births attended by midwives. Approximately the same degree of statistical association exists for infants of the white race but not for infants of other races.

DEMAND FOR FREE HEALTH SERVICE DECREASING

A comparison of the first quarter of 1941 with the same quarter in 1942 shows that there has been an increase in hospital inpatient care and a decrease in all other health programs, including clinic visits, home medical visits, medical social service, mental hygiene clinics, public health nursing and school health programs. The increase in hospital patient days is largely accounted for by increased service given in hospitals for tuberculosis. An analysis of the total inpatient days shows that there has been a decrease of 12.5 per cent in free patient days and an increase of 11.9 per cent in days paid for. This is primarily a reflection of improved economic conditions. When maternity care alone is considered there is a decrease of 6 per cent in those provided care under public auspices and an increase of 26 per cent in those paid for by the patients. The largest decrease (29 per cent) was in medical services provided by social agencies in the home and in doctors' visits to patients' homes reported by health and welfare agencies. These figures were obtained by a sampling test covering forty-five urban areas and other hospital statistics.¹

THE JOURNAL OF THE NATIONAL MALARIA SOCIETY

The first volume of a new journal devoted to malaria has just appeared. It is the official organ of the National Malaria Society, formerly the National Malaria Committee. It is to be made a quarterly of fifty pages as soon as financial support and sufficient material justify such action. The first issue, which is the entire volume for 1942, contains some sixteen original contributions on various phases of the malaria problem. In view of the worldwide importance which is attached to control of malaria this new journal will doubtless serve as a highly useful medium for disseminating information.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

PROCUREMENT OF MEDICAL OFFICERS FOR THE ARMY IN 1943

NOTE—The following is an official statement from the Medical Corps of the United States Army indicating the procedure to be followed in procuring medical officers for the Army during 1943—LD

The Surgeon General is responsible for the procurement of medical officers for the Army of the United States. There is an Office Procurement Service set up by the War Department for the procuring of applications of individuals for commission in the Army. The War Manpower Commission has set up a Procurement and Assignment Service for Physicians, Dentists and Veterinarians to designate the individuals who are essential to the community and those available for duty with the armed forces.

In order to coordinate the work of these two agencies the Surgeon General has outlined the following procedure for the procurement of officers during the year 1943.

The state chairmen of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians will from time to time prepare lists of individuals who are declared available for duty. Their names will be sent to the Central Office of the War Manpower Commission in Washington, D. C. There a card will be prepared and sent to the individual informing him of the fact that he has been classified as available for military service and requesting that he send the attached card to the state chairman of the Procurement and Assignment Service signifying his interest in applying for a commission, and stating his preference for duty with the Army or Navy. Those who choose to serve in the Army may request that their papers be processed with the idea of assigning them to duty with the Air Forces.

The state chairmen will furnish the candidate to the designated field office of the Office Procurement Service of the War Department. This office will request the individual physician, dentist or veterinarian to complete the proper application blanks and return them to that office and to have a final type physical examination, which will be accomplished at the nearest properly equipped army post.

The Office Procurement District's office will forward the papers to the Surgeon General in Washington, who will then review the application for commission

in the Medical Corps, Army of the United States. Those applications with the notation "Air" as designated will be referred to the Office of the Air Surgeon for further classification and assignment. Those applicants who are favorably considered will be notified at the earliest possible date by the Office of the Adjutant General that their recommendation is accepted and will receive orders to proceed to their proper station.

It is hoped by following this procedure that the Surgeon General will be able to provide an adequate medical service for our armed forces. It is contemplated that all individuals who are classified as essential to the civilian medical needs will not be asked to apply for a commission. No individual so classified need contact the Surgeon General or apply for a commission unless he can make arrangements with the state chairman of the Procurement and Assignment Service to have his classification changed from essential to available. The cooperation and interest of all physicians who are interested in military medical service will be appreciated, in that by proper application and processing of their case it will be much easier to provide necessary medical care for all parts of both the civilian and military services.

Concurrent with the changes in the military and civilian requirements for physicians and the changes in the recruiting procedures, the Surgeon General has announced the following policy, which will govern action to be taken in the consideration of ages and grades of initial appointments on all applicants effective Feb 15, 1943.

1. Eligible applicants for appointment in the Medical Corps, Army of the United States under the age of 38 will be appointed in the grade of first lieutenant only.

2. Eligible applicants between the ages of 38 and 55 will be appointed in the numbers and in the grade for which specific position vacancies exist.

There is an acute need for medical officers under 38 years of age. Applications are being solicited from physicians of this age group in those localities that have not furnished their quotas of physicians and where they are designated by the Procurement and Assignment Service as available for military service.

Appointments will be made by the Adjutant General of eligible applicants recommended by the Surgeon General and approved by the Secretary of War's Personnel Board.

NAVY

NAVAL MEDICAL SCHOOL GRADUATES

The following medical officers recently completed the basic course of instruction at the Naval Medical School Bethesda, Maryland. Included also is each officer's home town and the hospital in which he served an internship. These medical officers were all lieutenants (jg) at the time of the completion of the course on November 28 except Ferdinand E. Chatard, Dana Alexander Weeks and Harold E. Williamson, who are lieutenants.

CIVILIAN DEFENSE

THE EMERGENCY WATER SUPPLY PROGRAM

The Office of Civilian Defense Washington D C issued on December 22 Circular Medical Series No 26 which contains the following recommendations for the guidance of state and local councils of defense in the emergency water supply program.

1 *Appointment and Duties of State Water Supply Coordinator*—Responsibility for the organization and administration of the state emergency water supply program should be delegated to the state water supply coordinator, to be appointed as an official of the state defense council on recommendation of the state department of health. A member of the state agency having supervision over municipal water supplies would be a desirable appointee. He should be provided with technical and clerical assistants.

The state water supply coordinator should be responsible for the administration and organization of the state emergency water supply program and should represent the state in all matters pertaining to water supply as related to civilian defense. He should work in close cooperation with the state department of health or other state agency responsible for waterworks and with the regional sanitary engineers of the Office of Civilian Defense.

His duties should be to (1) prepare plans rules and regulations for adoption by the state defense council and be responsible for administering the rules and regulations adopted. (2) institute and develop the mutual aid plan with the state as suggested in U S Office of Civilian Defense Sanitary Engineering Bulletin

No 1 and be responsible for its operation at the state level during emergencies. (3) coordinate the emergency water supply program with other civilian defense activities at the state level. (4) develop a program for and coordinate the efforts of zone water supply coordinators and (5) cooperate with the regional sanitary Engineer U S Office of Civilian Defense and develop interstate mutual aid.

2 *Appointment and Duties of Assistant State (Zone) Water Supply Coordinators*—To facilitate execution of this program zones or districts should be established with boundaries coterminous with other political or administrative divisions. Assistant state (zone) water supply coordinators should be appointed for these areas by the appointing authority on recommendation of the state water supply coordinator. Assistant state (zone) water supply coordinators should be selected from leading water works officials residing in the area. To assist this official an engineer from one of the public health departments in the area may be appointed as deputy or assistant zone water supply coordinator. Individuals or small communities may also be designated by the zone water supply coordinator on a temporary basis to make special studies or investigations.

The duties of the assistant state (zone) water supply coordinator should be to (1) negotiate among the localities within the zone pacts for the operation and financing of the mutual aid plan and be responsible for the administration of the mutual aid program within the zone during emergencies. (2) establish and maintain contact with local councils of defense and integrate the local emergency water supply program within the state

program, and (3) advise local waterworks authorities on (a) technical aspects of emergency water works engineering, (b) recruitment and training of auxiliary personnel and emergency training of regular personnel, (c) procurement of materials and funds to execute plans and (d) integration of emergency water supply program with other local protective services

3 In states where emergency water supply programs are being carried on by regular state departments as an adjunct to their regular duties, it is recommended that the program be officially recognized as a part of the civilian defense program of the state and its leaders be designated, as outlined in this letter

4 In the administrative organization and operation of the emergency water supply program it is most important that

there be integration of the activities of local waterworks officials, state water supply coordinators and their assistant (zone) coordinators, and the regional sanitary engineers and the sanitary engineering section of the medical division of the U S Office of Civilian Defense

WOMEN TO CARE FOR CHILDREN

The Office of Civilian Defense, Washington, D C, announced on January 2 that civilian defense classes throughout the country have trained 38,676 women to care for war workers' children in day nurseries. These figures are based on reports from 745 local defense councils. Three hundred other councils have not yet reported.

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

Nya Dagligt Kålahanda of Nov 6, 1942 reports from Berlin that as a result of a court verdict in the case of a man who had acted against his doctor's instructions and thus prolonged his illness, every German worker who falls ill and is unable to work is in duty bound to do everything possible to recover as soon as possible and avoid everything that is likely to make his condition worse or delay his recovery. He is absolutely bound to follow the doctor's instructions and should he fail to do this or should he otherwise neglect his duty to recover he cannot count on receiving his wages during the time of his illness.

The *Völkischer Beobachter* Vienna edition of Nov 1, 1942 states that from the 250,000 applications with which the medical council is dealing at present it must be concluded that apart from the several thousand patients who are in hospitals just now, there are 250,000 Viennese who are sick, this means that every seventh person is suffering from some ailment or other, apart from those weaklings who get contusions, sprains and broken ribs through riding in a tram between the Margaretenplatz and the Laudongasse. The diseases to which we are referring here are of a worse and more secretive character. No plaster casts, x-rays or medicine will help these patients. The only thing that could really save them from collapse is additional food, i.e., meat, rice, eggs, butter, fats, unskimmed milk and coffee. Because people lack this additional food, they feel sick and consult the doctor.

The *Brüsseler Zeitung*, Oct 17, 1942, reports that the German Academy in Brussels gives lectures for Belgium doctors 'thus enabling them to learn the German medical terminology and to hear about the development of hygiene in Germany.'

According to *Minsker Zeitung* of Oct 15, 1942, Dr Wagner has published an article in the *Deutsches Ärzteblatt* on the measures taken to prevent the spread of epidemics in the Ostland which gives a complete survey of the conditions prevailing in the commissariats Ostland and Ukraine. It is said, *inter alia*:

'Statistics of the epidemics published by the Soviet authorities are false and are intended for propaganda purposes only. It can be assumed with certainty that on the average two or three million people succumbed annually to malaria in European Russia, of whom half were in the Ukraine. 200,000 to 500,000 to spotted typhus, particularly in White Ruthenia and in the northern Ukraine, and at least as many to typhus and dysentery.'

'In 1942 every one had to report for medical examinations at first every four weeks, as from April last every week, and in the Ukraine every ten days. In addition measures were introduced in the Ostland to check the spread of lice among the population. A special scientific department was established in Riga for dealing with the spread of epidemics.'

Special importance was attached to the obtaining of vaccine lymph, medicaments, disinfectants and so on. These had first to be imported from Germany, however, serum institutes had been established in Kaunas, Riga, Dorpat, Kiev and Dnepropetrovsk on the German model.

As stated in *Uj Magyarasag* of Oct 14, 1942 a central x-ray institute has been founded in Kolozsvár (Cluj) and is now in operation. It contains wards with 15 beds and with 2 beds

It possesses radium to the value of 50,000 pengos and is primarily concerned with cancerous diseases.

According to the *Hamburger Fremdenblatt* of Oct 30, 1942 the OKW has explained that also medical officers and personnel may win the *Sturmabzeichen* if they operate under the same fighting conditions as the attacking infantry and care for the wounded in areas where there is close fighting. Similarly they may win the *panzerkampfwagenabzeichen* if they attend to the wounded during the fighting while riding in tanks.

Frois Allot of Oct 8, 1942 states that the physiologist Richet has stated that the French food position is particularly dangerous for the young. Nine out of ten children are threatened with tuberculosis and on the basis of the food rations nine tenths of the adults receive 1,030 calories instead of 3,000-4,000, which is necessary for working persons. Heavy workers receive 1,210 calories which is less than the need for completely inactive men, i.e., 2,300 calories.

METHYL ALCOHOL UNDER COMPLETE ALLOCATION

Because of increased demands for military requirements, methyl alcohol, or methanol, was placed under complete allocation, effective January 15 with the issuance by the Director General for Operations of General Preference Order M-31 as amended. According to the Office of War Information there will be an apparent shortage for 1943 of about 10 million gallons excluding the methanol from wood distillation, unless the use of methanol for unessential items is curtailed as rapidly as possible. The increase in demand is caused primarily by the requirements for formaldehyde to produce hexamethylenetetramine, an ingredient in explosives used by both the United States and Great Britain. It also is caused by increasing demands for methanol to be used in the manufacture of methyl methacrylate resins for military aircraft and by increasing demands for hexamethylenetetramine for Russia.

BUTTER MAKERS TO RESERVE 30 PER CENT OF PRODUCTION

Manufacturers of creamery butter have been directed by Secretary of Agriculture Claude R. Wickard to set aside 30 per cent of their monthly production for direct war requirements beginning February 1. The order, Food Distribution Order No 2, was issued to obtain sufficient supplies of butter to meet the needs of the armed forces and for minor export to Allied nations.

CLASSIFICATION OF COMMISSIONED OFFICERS, PUBLIC HEALTH SERVICE

The National Headquarters of the Selective Service System, Washington, D C, issued Local Board Release No 174 on December 26 which directed that registrants who are commissioned officers of the Public Health Service or Public Health Service Reserve, whether on active duty or in an inactive status, will be classified in class IV-B.

ORGANIZATION SECTION

THE PHYSICIAN'S FEDERAL INCOME TAX—1943

PREPARED BY THE BUREAU OF LEGAL MEDICINE AND LEGISLATION

The Revenue Act of 1942 has been correctly described as the greatest revenue raising measure in the history of our country and finds its justification in the tremendous needs of our war program, needs having to do with the actual expenditures for war purposes plus needs in relation to inflation potentialities. The act not only will spiral the tax burden of prior taxpayers but will bring into the income tax picture many millions of persons whose low income has heretofore constituted exempt income. Already plans are under way for additional legislation to raise still more revenue, and the tax burden may reasonably be expected to assume even greater proportions.

During the time when the new act was being formulated by congressional committees and when it was being discussed first in the House and in the Senate advocates of the so-called Ruml pay-as-you-go plan for the payment of individual income taxes persistently suggested the undesirability of a continuation of the existing practice of taxing during a succeeding year the income received by an individual during a preceding year. There has recently been renewed interest in this plan, and the possibility is not remote that a changed policy may be adopted in the reasonably near future, perhaps by March 15. The President, the Treasury Department and leaders in the Congress have openly espoused the theory of the pay-as-you-go plan, and this espousal has given rise to some doubt on the part of taxpayers concerning the filing of returns this year. The doubt has been apparently so widespread as to call for a public statement by the chairman of the House Committee on Ways and Means, the committee that will initiate any change in our tax procedures, advising taxpayers that a return must be filed on or before March 15 and that that return must be based on the provisions of the 1942 Revenue Act. Despite the uncertainties of the future as to the pay-as-you-go matter, therefore it is essential that the broad requirements of the new act be fully understood by federal income tax payers.

The Revenue Act of 1942 reduces the personal exemptions of single persons from \$750 to \$500 and of married persons or heads of families from \$1,500 to \$1,200. It reduces the credit for dependents from \$400 to \$350. An additional exemption is allowed members of the armed forces below the grade of commissioned officers. If a serviceman is single then the first \$250 of the service pay he received during 1942 is exempt. If he is married or the head of a family, then the first \$300 is exempt. The determination of a taxpayer's status in the armed forces and his family status will be made as of the end of the taxable year for the purpose of this particular exemption.

The basic rate of taxation is increased from 4 per cent to 6 per cent. The surtax rate is elevated from 6 per cent on the first \$2,000 of surtax net income to 13 per cent with a constant increase in rates for

incomes in the higher brackets. The earned income credit of 10 per cent remains as heretofore. This credit may be claimed in connection with the normal tax but not with the surtax.

The act continues the provision for a simplified tax schedule for use by taxpayers having gross incomes of \$3,000 or less, derived wholly from salaries, wages or other forms of compensation for personal services, dividends, interest, rents, annuities or royalties. The use of the simplified form remains optional. If the taxpayer has no deductions, it will, generally speaking be to his advantage to use this form. If he has deductions he should tentatively figure the tax under both the regular method and the optional method and use whichever method happens to be to his advantage.

Returns under the new act need not be made under oath, as has been the requirement heretofore. This will relieve taxpayers of the petty annoyance of having their returns sworn to before a notary public or some other official authorized to administer oaths. The taxpayer, however, who falsifies a return will be subject to heavy penalties even though he is not required to execute the return under oath.

WHO MUST FILE RETURNS

In General—1 Returns must be filed by every unmarried person and by every married person not living with spouse, if gross income during 1942 was \$500 or more.

2 Returns must be filed by every married person who lived with spouse, if gross income during 1942 was \$1,200 or over. If both husband and wife had income and their combined gross income was \$1,200 or over, they must either file separate returns or if both are citizens or residents of the United States and if they were living together at the end of the taxable year, they may file a joint return. If a person was married and lived with spouse for only part of 1942, special rules apply with respect to the filing of returns, and physicians who come within this classification should read carefully the instructions given on the tax return blanks.

If the status of a taxpayer, so far as it affects the personal exemption or credit for dependents, changed during the year, the personal exemption and credit must be apportioned, under rules and regulations prescribed by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury, in accordance with the number of months before and after such change. For the purpose of such apportionment a fractional part of a month should be disregarded unless it amounts to more than half a month, in which case it is to be considered as a month.

Physicians in Military or Naval Service—The fact that a physician may be in service does not of itself excuse a failure to file a return, for the income tax act applies to persons in service as well as to persons engaged in civilian activities. Physicians who have

gone into service, therefore, should if at all possible file complete returns before the deadline. While, unfortunately, definite regulations have not been issued to cover the situation, it is understood that, if because of the inaccessibility of necessary records a physician in service is unable to file a complete return, he may file a tentative return on which he must estimate his income, deductions and tax as best he can and indicate on the return his reasons for following this procedure. He will be required at a later date to file a complete return, and necessary adjustments in the tax will be made.

If a physician in service is on duty outside the United States no income tax return or payment of any income tax will become due, generally speaking, until the fifteenth day of the third month following the month in which the physician ceases (except by reason of death or incompetency) to be a member of the military forces on sea duty or in service outside the continental United States, or the fifteenth day of the third month following the month in which the present war is terminated as proclaimed by the President, whichever may be the earlier.

GROSS AND NET INCOMES WHAT THEY ARE

Gross Income—A physician's gross income is the total amount of money received by him during the year for professional services, regardless of the time when the services were rendered for which the money was paid, assuming that the return is made on a cash receipts and disbursements basis, plus such money as he has received as profits from investments and speculation and as compensation and profits from other sources.

If a physician receives a salary as compensation for services rendered and in addition thereto living quarters or meals, the value to the physician of the quarters and meals so furnished ordinarily constitutes income subject to tax. If, however, living quarters or meals are furnished for the convenience of the employer the value thereof need not be computed and added to the compensation otherwise received by the physician. As a general rule, the test of "convenience of the employer" is satisfied if living quarters or meals are furnished to a physician who is required to accept such quarters and meals in order to perform properly his duties. For example, if a physician employed by a hospital is subject to immediate service at any time during the twenty-four hours of the day and therefore cannot obtain quarters or meals elsewhere without material interference with his duties and on that account is required by the hospital to accept the quarters or meals furnished by it, the value thereof need not be included in the gross income of the physician.

Net Income—Certain professional expenses and the expenses of carrying on any enterprise in which the physician may be engaged for gain may be subtracted as "deductions" from the gross income, to determine the net income on which the tax is to be paid. An "exemption" is allowed, the amount depending on the taxpayer's marital status during the tax year as stated before. These matters are fully covered in the instructions on the tax return blanks.

Earned Income—In computing the normal tax, but not the surtax, there may be subtracted from net income from all sources an amount equal to 10 per cent of the earned net income, except that the amount so subtracted shall in no case exceed 10 per cent of

the net income from all sources. Earned income means professional fees, salaries and wages received as compensation for personal services, as distinguished from receipts from other sources.

The first \$3,000 of a physician's net income from all sources may be regarded under the law as earned net income, whether it was or was not in fact earned within the meaning set forth in the preceding paragraph. Net income in excess of \$3,000 may not be claimed as earned unless it in fact comes within that category. No physician may claim as earned net income any income in excess of \$14,000.

PHYSICIANS IN MILITARY OR NAVAL SERVICE

As previously pointed out, physicians in service are as much subject to the income tax law as are physicians engaged in civilian practice. The service pay of such physicians must be reported as income. Commutation of quarters and rental value of quarters occupied by medical officers, however, are not taxable income.

If the ability of physicians in service to pay income taxes is materially affected by such service, payment of the tax falling due before or during the service may be deferred for a period extending not more than six months after termination of service. This deferment is authorized by section 513 of the Soldiers' and Sailors' Civil Relief Act of 1940 and applies to all members of the Army, Navy, Marine Corps and Coast Guard, and to all officers of the United States Public Health Service detailed by proper authority for duty either with the Army or Navy, on active duty or undergoing training or education under the supervision of the United States preliminary to induction into service. This does not apply to the tax imposed on employers by section 1400 of the Federal Insurance Contributions Act. This deferment is not automatic. The taxpayer must present evidence to show that his ability to pay the tax is materially impaired by reason of military service. Proof of that impairment should be submitted at the time the tax is due on a form procurable from the offices of the collectors of internal revenue. A copy of the form was reproduced in the Feb. 28, 1942 issue of *THE JOURNAL* on page 737.

THE VICTORY TAX

The physician need give no consideration to the new 5 per cent Victory tax in making his return on or before March 15. As explained in *THE JOURNAL*, Dec. 5, 1942, this tax does not apply to income received during 1942 although physicians who are classifiable as employees will periodically have the tax withheld from their salaries during 1943.

TAXATION OF ACCOUNTS RECEIVABLE

The Revenue Act of 1942 remedies an unjust method of taxation that has heretofore prevailed in connection with the unpaid accounts on the books of a taxpayer at the time of his death. Under prior law, for the year of death, the value of such accounts has been included as income and subject to the income tax rates, even though the taxpayer actually received no income at all therefrom. Hereafter the value of the unpaid accounts will not be considered as a part of the income of the decedent for the year of death but will be taxable when paid, as a part of the income of the person receiving the money. A detailed discussion of this matter was published in *THE JOURNAL*, Jan. 10, 1942, page 149.

DEDUCTIONS FOR PROFESSIONAL EXPENSES

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless he is prepared to prove the expenditure by competent evidence. So far as practicable, accurate itemized records should be kept of expenses and substantiating evidence should be carefully preserved. The following statement shows what such deductible expenses are and how they are to be computed.

Office Rent—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment for use as a residence as well as for office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in such dwelling house or apartment, he may not, however, deduct any part of the rent of such house or apartment as professional expense, to entitle him to such a deduction he must have an office there, with regular office hours. If a physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

Office Maintenance—Expenditures for office maintenance, as for heating, lighting, telephone service and the services of attendants are deductible.

Supplies—Payment for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using, for instance, dressings, clinical thermometers, drugs and chemicals. Professional journals may be classified as supplies and the subscription price deducted. Amounts currently expended for books, furniture and professional instruments and equipment, "the useful life of which is short," generally less than one year, may be deducted, but if such articles have a more or less permanent value their purchase price is a capital expenditure and is not deductible.

Equipment—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment such as has been described for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical and laboratory equipment of more or less permanent nature and instruments and appliances constituting a part of the physician's professional outfit to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment and the purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired nevertheless it may be recovered through depreciation deductions taken year by year over its useful life, as described later.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductible each year as depreciation. The amount depends to some extent on the nature of the property and on the extent and character of its use. The length of its useful life should be the primary consideration. The most that can be done is to suggest certain average or normal rates of depreciation for each of several classes of

articles and to leave to the taxpayer the modification of the suggested rates as the circumstances of his particular case may dictate. As fair normal or average rates of depreciation, the following have been suggested: automobiles, 25 per cent a year, ordinary medical libraries x-ray equipment physical therapy equipment, electrical sterilizers surgical instruments and diagnostic apparatus 10 per cent a year office furniture, 5 per cent a year.

The principle governing the determination of all rates of depreciation is that the total amount claimed by the taxpayer as depreciation during the life of the article, plus the salvage value of the article at the end of its useful life, shall not be greater than its purchase price or, if purchased before March 1913 either its fair market value as of that date or its original cost, whichever may be greater. The physician must in good faith use his best judgment and claim only such allowance for depreciation as the facts justify. The estimate of useful life, on which the rate of depreciation is based should be carefully considered in his individual case.

Medical Dues—Dues paid to societies of a strictly professional character are deductible. Dues paid to social organizations, even though their membership is limited to physicians, are personal expenses and not deductible.

Postgraduate Study—The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible.

Traveling Expenses—Traveling expenses including amounts paid for transportation, meals and lodging, necessarily incurred in professional visits to patients and in attending medical meetings for a professional purpose, are deductible.

Automobiles—Payment for an automobile is a payment for permanent equipment and is not deductible. The cost of operation and repair, and loss through depreciation are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance, repairs, garage rental (when the garage is not owned by the physician), chauffeurs' wages and the like.

Deductible loss through depreciation of an automobile is the actual diminution in value resulting from obsolescence and use and from accidental injury against which the physician is not insured. It depreciation is computed on the basis of the average loss during a series of years, the series must extend over the entire estimated life of the car, not merely over the period in which the car is possessed by the present taxpayer.

If an automobile is used for professional and also for personal purposes—as when used by the physician partly for recreation, or so used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted. A physician doing an exclusive office practice and using his car merely to go to and from his office cannot deduct depreciation or operating expenses. He is regarded as using his car for his personal convenience and not as a means of gaining a livelihood. What has been said in respect to automobiles applies with equal force to horses and vehicles and the equipment incident to their use.

MISCELLANEOUS

Contributions to Charitable Organizations—For detailed information with respect to the deductibility of charitable contributions generally physicians should

consult the official return blank or obtain information from the collectors of internal revenue or from other reliable sources. A physician may not, however, deduct as a charitable contribution the value of services rendered an organization operated for charitable purposes.

Bad Debts—Physicians who make their returns on a cash receipts and disbursements basis, as most physicians do, cannot claim deductions for bad debts.

Taxes—Taxes generally, either federal or state, are deductible by the person on whom they are imposed by law. Both real and personal property taxes are deductible, but so-called taxes, more properly assessments, paid for local benefits, such as street, sidewalk, and other like improvements, imposed because of and measured by some benefit inuring directly to the property against which the assessment is levied, do not constitute an allowable deduction from gross income. Physicians may deduct state gasoline taxes and state sales taxes. In some states sales taxes are imposed on the seller, but, if they are passed on to the buyer, the latter may deduct them.

State income and use taxes are deductible, federal income taxes are not. Among the federal taxes that a physician may deduct are those on admissions, dues, initiation fees, safety deposit boxes, tax on telegraph, telephone, cable and radio messages, and the federal use tax on automobiles. State automobile license fees are deductible. If a state or local fee is imposed for regulatory purposes, and not to raise revenue, the fee may not ordinarily be deducted as a tax. If such fees, however, are classifiable as a business expense, they are deductible as such. Annual registration fees imposed on physicians probably come within the category of regulatory fees and should be deducted as a business expense rather than as taxes. Local and state occupational taxes imposed on physicians are deductible either as taxes or as a business expense, depending on the purpose for which the tax is imposed.

The excise taxes imposed on employers by section 804, title VIII, and section 901, title IX, of the Social Security Act, commonly referred to as old age and unemployment benefit taxes, are deductible annually by employers in computing net income for federal income tax purposes. If the taxpayer's return is made on a cash basis, as are the returns of practically all physicians, the taxes are deductible for the year in which they are actually paid. If the return is made on an accrual basis, the taxes are deductible for the year in which they accrue, irrespective of when they are actually paid. Employees, including physicians whose employment brings them within that category, may not deduct the tax imposed on them by section 801, title VIII, of the Social Security Act, generally referred to as the old age benefits tax. If, however, the employer assumes payment of the employee's tax and does not withhold the amount of the tax from the employee's wages, the amount of the tax so assumed may be deducted by the employer, not as a tax paid but as an ordinary business expense.

Medical Expense—A taxpayer may deduct amounts expended for medical, dental and hospital care, not compensated for by insurance or otherwise, including amounts paid for accident and health insurance, according to a prescribed formula. Deductions will be permitted to the extent that such expenses exceed 5 per cent of the net income of the taxpayer but not in excess

of \$2,500 in case of the head of a family, or \$1,250 in case of other individual taxpayers.

Equipment Necessitated by Military Service—The cost of equipment of an Army officer to the extent only that it is especially required for his profession and does not merely take the place of articles required in civilian life is deductible. The cost of a uniform is considered a personal expense and hence not deductible.

Laboratory Expenses—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

Losses by Fire or Other Causes—Loss of and damage to a physician's equipment by fire, theft or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

Insurance Premiums—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

Expense in Defending Malpractice Suits—Expense incurred in the defense of a suit for malpractice is deductible as a business expense.

Sale of Spectacles—Oculists who furnish spectacles etc., may charge as income money received from such sales and deduct as an expense the cost of the article sold. Entries on the physician's account books should in such cases show charges for services separate and apart from charges for spectacles, etc.

NONTRADING OR NONBUSINESS EXPENSES

A new provision in the Revenue Act of 1942 permits, in the case of an individual, the deduction of all the ordinary, necessary expenses paid or incurred during the taxable year for the production or collection of income, or for the management, conservation or maintenance of property held for the production of income. While the phraseology of this provision is very broad, the Commissioner of Internal Revenue has by regulation ruled that the following expenses, among others, are not deductible under it: Commuters' expenses, expenses of taking special courses of training, expenses in seeking employment or in placing one's self in a position to begin rendering personal services for compensation, bar examination fees and other expenses incurred in securing admission to the bar, and corresponding fees and expenses incurred by physicians, dentists, accountants and other taxpayers for securing the right to practice their respective professions.

OFFICIAL NOTES

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the medical department of the United States Army and the United States Navy are on the air each Saturday at 5 p m Eastern War Time (4 p m Central War Time, 3 p m Mountain War Time, 2 p m Pacific War Time). An exception is the Chicago area, where the broadcasts are heard by transcription at 8 p m Central War Time Saturdays on station WMAQ.

Titles, subjects and guest speakers where scheduled for the next five programs are as follows:

- | | | |
|-------------|------------------------|--|
| January 30 | Wake Up America | social hygiene and the war |
| | Guest speaker | Surg Gen Thomas Parran United States Public Health Service |
| February 6 | Rumor Monger | morale in wartime |
| February 13 | The Heart of a Soldier | strong hearts in the Army |
| February 20 | Come and Get It | —the story of how our fighting men are fed |
| February 27 | Community Fortress | —health on the home front |

HOMEMAKERS' PROGRAM ON WLS

Beginning January 28 and each Thursday thereafter to and including May 27, the American Medical Association will broadcast during the Homemakers Hour on radio station WLS Chicago, a program intended to be helpful to the mothers of young children under the title *Before the Doctor Comes*. Common home health problems will be discussed in an interview program in which Dr W W Bauer, Director of the Bureau of Health Education, will be interviewed by Mrs Harriet H Hester. The program will be heard on radio station WLS (890 kilocycles) between 1 30 and 2 p m as a part of the Homemakers' Hour. Following are the topics for the first three broadcasts:

- | | |
|-------------|------------------------------|
| January 28 | The Child with Sniffles |
| February 4 | The Child with a Sore Throat |
| February 11 | The Child with a Cough |

This is not a network program but station WLS is a 50 000 watt, clear channel station which has a primary daytime coverage of the states of Wisconsin Michigan, Indiana and Illinois with portions of Iowa, Missouri Ohio and occasionally Kentucky. The audience is 60 to 70 per cent down state.

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Bills Introduced—S 242, introduced by Senator Capper, Kansas, provides for the issuance of a license to practice osteopathy in the District of Columbia to Maria G Waksmundzka. H R 741, introduced by Representative Randolph, West Virginia, provides for the registration of births in the District of Columbia that were not registered when the births occurred in the District.

MEDICAL BILLS IN CONGRESS

Bills Introduced—S J Res 12, introduced by Senator Wheeler, Montana, proposes to amend an act passed by the Seventy-Seventh Congress to regulate the interstate sale of dentures by postponing the effective date of that act for a period of six months. S 72, introduced by Senator McNary, Oregon, proposes service pensions to all persons who served ninety days in foreign service under the jurisdiction of the Quartermaster General, Surgeon General of the United States Army, the Secretary of the Navy or the Marine Corps during the Spanish-American War, including the Philippine Insurrection and the Chinese Boxer Rebellion. S 77, introduced by Senator Caraway, Arkansas, proposes to authorize the Secretary of the Treasury to determine the total amount collected by the federal government from each physician during the period June 1, 1920 to June 30, 1931 for the privilege of prescribing the hot waters from the Hot Springs National Park and to refund to each such physician the total amount so determined to have been collected from him, with the proviso that not more than \$660 may be returned to any one physician. S 137, introduced by Senator Davis, Pennsylvania, provides that no person shall be discriminated against, in the administration of the civil service laws and regulations, in any case because of his or her blindness or impaired visual acuity. S 180, introduced by Senator LaFollette, Wisconsin, provides for the vocational rehabilitation education training and the rendition of other services to persons disabled while members of the armed forces or disabled in war industries or otherwise. S 186, introduced by Senator White for himself and Senator Brewster both of Maine, proposes to create a Division of Water Pollution Control in the United States Public Health Service. S 187, introduced by Senator Walsh, Massachusetts, provides for vocational rehabilitation and the return to civil employment of certain persons disabled under circumstances entitling them after discharge or separation from the military or naval forces of the United States to a pension or retirement pay. S 216, introduced by Senator Reynolds, North Carolina, proposes to amend certain provisions of the National Defense Act of June 3, 1916 by eliminating the Medical Administrative Corps in the Medical Department of the regular

Army and substituting therefor a Pharmacy Corps. S 250 introduced by Senator Clark, Missouri, proposes to amend existing veterans' regulations so as to grant hospitalization, domiciliary care and burial benefits to any officer enlisted man member of the Army Nurse Corps (female) or Navy Nurse Corps (female) employed in the active military or naval service of the United States on or after Dec 7, 1941 and before the termination of the present war. S 281, introduced by Senator Green, Rhode Island, proposes to amend and extend the provisions of the Social Security Act, to extend the coverage of federal old age and survivors insurance, to provide insurance benefits for workers permanently and totally disabled to provide hospitalization benefits, to provide special federal aid to states for public assistance to provide federal grants to states for general public assistance and to amend the provision for federal grants to states for old age assistance aid to dependent children and aid to the blind. H R 121 introduced by Representative Cannon, Missouri, provides that all public laws granting medical and hospital treatment, domiciliary care, compensation and other allowances, pensions disability allowance and retirement pay to veterans and the dependents of veterans of the World War which were repealed in 1933 shall be reenacted. H R 375, introduced by Representative Voorhis, California, proposes to amend the Social Security Act so as to provide that each state shall have the exclusive right to adopt its own interpretation of the phrases 'needy individuals who are blind' and 'blind individuals who are needy'. The purpose of the bill is to encourage the states to make more adequate provisions for blind persons. H R 376 introduced by Representative Voorhis, California, undertakes to amend the Social Security Act so that each state may have the exclusive right to adopt its own interpretation of the phrases 'needy individuals' as used in the act. The purpose of this bill is to encourage the states to make more adequate provisions for aged persons. H R 661 introduced by Representative Rogers, Massachusetts, proposes for the purpose of enabling the Public Health Service to assist state counties cities or other political subdivisions of the states to extend and improve measures through public and private institutions and organizations for the diagnosis treatment and control of cancer including the provision of hospital diagnostic clinic and other facilities for the diagnosis and treatment of persons suffering from cancer or suspected of suffering from this disease that there be appropriated for the first fiscal year of the operation of the law the sum of \$2 300 000 and for each fiscal year thereafter such sum as may be necessary to carry out its purpose. H R 723 introduced by Representative Green, Florida, proposes to authorize an appropriation of \$1 550 000 for the con-

struction of a marine hospital in the state of Florida the site to be selected by the Federal Board of Hospitalization. H R 724, introduced by Representative Green, Florida, proposes an appropriation of \$2,500,000 for the construction of a marine hospital at Jacksonville, Fla. H R 728, introduced by Representative Green, Florida, proposes to authorize the Administrator of Veterans' Affairs within the limits of Veterans Administration facilities, to furnish necessary dental care and treatment including necessary dental appliances and transportation to and from a Veterans Administration facility, to veterans of any war (including the Indian wars, the Boxer Rebellion and the Philippine Insurrection) who were not dishonorably discharged and are not entitled to the benefits provided by the bill under any law or veterans regulation in effect at the present time. H R 735, introduced by Representative Welch, California, proposes that all persons who served in a civilian capacity under the jurisdiction of the Quartermaster General during the war with Spain, the Philippine Insurrection or the China Relief Expedition on vessels owned by the United States and engaged in the transportation of troops, supplies, ammunition or materials of war, and who were discharged for disability incurred in such governmental service in line of duty, shall be furnished medical and hospital treatment and domiciliary care in Veterans' Administration facilities in the same manner and to the same extent as provided for veterans of any war. H R 739, introduced by Representative Van Zandt, Pennsylvania, and H R 891 introduced by Representative Rankin, Mississippi, provide for the rehabilitation of disabled veterans of the present war. H R 782, introduced by Representative Voorhis, California, proposes to direct the Administrator of Veterans' Affairs to promulgate regulations pertaining to service connection containing additional provisions requiring that as to those veterans who are shown to have been engaged in combat with an enemy of the United States or who are shown to have been subjected to other arduous conditions of military or naval service any subsequent disability which could have resulted by way of incurrence or aggravation traceable to such veterans' active military or naval service shall be considered as directly due to or aggravated by such service in line of duty. H R 783, introduced by Representative Voorhis, California, proposes to grant permanent and total disability ratings to veterans suffering from severe industrial inadaptability as a result of war service. H R 786, introduced by Representative Tolson, California, proposes to amend section 40 of the United States Employees Compensation Act so as to authorize chiropractors to treat beneficiaries of that act. H R 788, introduced by Representative Tolson, California, proposes to amend the Social Security Act so as to provide grants to states for needy disabled adults. H R 789, introduced by Representative Tolson, California, proposes to provide grants to the states for assistance in the rehabilitation of disabled persons incapacitated for normal employment. H R 790, introduced by Representative Rankin, Mississippi, provides that all compensation, pension and hospital privileges granted to veterans of the first world war, their widows and dependents shall be extended to veterans of the present war, their widows and dependents. H R 828, introduced by Representative Costello, California, proposes to authorize an appropriation of \$2,600,000 for the construction of a marine hospital in or near Los Angeles. H R 867, introduced by Representative Knutson, Minnesota, proposes to exempt from the operations of the Social Security Act associations furnishing medical care or hospitalization to members or their dependents if no part of the net earnings of the association inures to the benefit of any private shareholder or individual and if 75 per cent or more of the income consists of amounts collected from members or contributed by the employer for the sole purpose of making such payments and meeting expenses. H R 868, introduced by Representative Knutson, Minnesota, proposes to amend the Social Security Act by providing for grants to states for furnishing aid to needy individuals who are physically handicapped. H R 874, introduced by Representative Knutson, Minnesota, undertakes to amend the Selective Training and Service Act of 1940 by providing that each member of each local board shall receive as compensation for his services \$5 for each day on which he performs board duties and in addition shall receive travel expenses at the rate of 5 cents per mile and subsistence expenses while away from his official station on

duties of the board. H R 887, introduced by Representative Van Zandt, Pennsylvania, provides that any person who served in the military or naval forces of the United States during a recognized campaign or expedition and who was honorably separated from such service shall be granted hospitalization and domiciliary care by the Veterans' Administration subject to the same restrictions and limitations as are applicable to World War veterans. H R 889, introduced by Representative Van Zandt, Pennsylvania, proposes to provide total disability ratings for veterans with severe functional nervous diseases or psychoneurotic conditions. H R 891, introduced by Representative Voorhis, California, provides for the granting of permanent and total disability ratings to veterans suffering from severe industrial inadaptability as a result of war service. H R 899, introduced by Representative Kennedy, New York, provides compensation for injuries or death sustained by volunteer civilian defense workers in line of duty. The bill also provides that for any injury sustained by an air raid warden or other volunteer worker engaged in civilian defense while in the performance of duty, whether or not disability has arisen the United States shall furnish to the injured person all services, appliances and supplies prescribed or recommended by duly qualified physicians which, in the opinion of the United States Employees Compensation Commission are likely to cure or relieve or to reduce the degree or the period of disability or to aid in lessening the amount of the monthly compensation. H R 911, introduced by Representative Rees, Kansas, provides that any veteran entitled to civil service preference shall have the right to be examined and to qualify for appointment to any position under classified civil service, notwithstanding his need of a prosthetic appliance to overcome a handicap if the duties of the position for which qualification is sought can be performed by such veteran. H R 913, introduced by Representative Rankin, Mississippi, proposes to extend the privilege of hospitalization to veterans of World War II for the treatment of non-service connected disabilities and to provide for preference or hospitalization to those veterans who were discharged by reason of disability and to those entitled to benefits for service connected disabilities.

STATE MEDICAL LEGISLATION

Arizona

Bills Introduced—S 9 proposes the enactment of a premarital examination law. The certificate to be obtained by each applicant for a marriage license must be executed by a licensed physician and shall certify that the applicant has been given an examination and been found not to be infected with syphilis in a communicable stage. The standard serologic test required shall be made at a laboratory either within or without the state which has been approved by the state board of health and the physician's fees and charges for making the examination and issuing the certificate required shall not exceed \$3 for each person examined. S 13 proposes the enactment of an occupational disease act. Occupational disease is defined to mean a disease which is due to causes and conditions characteristic of and peculiar to a particular trade, occupation, process or employment and excludes all ordinary diseases of life to which the general public is exposed. Among other things, the bill proposes that in the event an employee though not actually incapacitated is found to be affected by silicosis or asbestosis, he may, subject to the approval of the commission, waive in writing full compensation for any aggravation of condition that may result from continuing in the hazardous occupation. In case of total incapacity or death as a result of the disease after waiver, however compensation not to exceed \$3,000, whether for incapacity, death or both shall nevertheless be payable. The proposed bill further provides for the appointment of an advisory medical council of three members who shall be licensed practitioners of medicine in good professional standing and qualified in the diagnosis and treatment of occupational diseases, at least one of whom shall be an experienced roentgenologist. The council shall conduct examinations, make reports on controverted medical questions and assist in any postmortem examination directed by the commission, and the report of such advisory medical council shall become part of the record of the case and be accepted and considered by the commission as expert medical testimony unless a special hearing is requested by the claimant.

for the purpose of examining or cross examining members of the council. S 23 proposes to empower the state department of health to commit any person known to be infected with a venereal disease to an institution for care and treatment and to detain and quarantine such person for such time as may be necessary. The proposal would further provide that a person willfully refusing to submit to treatment by the state board of health would be guilty of a misdemeanor.

Arkansas

Bill Introduced—S 13 proposes to amend the medical practice act by repealing Act No 368 of the Laws of 1941 which required an annual license and registration of licentiates and amended certain provisions regarding educational requirements and the granting of reciprocity certificates.

California

Bills Introduced—S 81 and A 186 propose to amend the sales tax by exempting therefrom the sale of medicines sold as dietary supplements or adjuncts. A 6 proposes to amend the osteopathic practice act by eliminating the existing requirement that osteopaths, at the time of the annual renewal of their licenses, present satisfactory evidence of the completion during the preceding year, of a minimum of thirty hours of professional educational work as approved by the osteopathic board. A 44 proposes to amend the Revenue and Taxation Code by exempting from the sales tax medicines or drugs, defined to include any substance or mixture of substances intended to be used internally or externally in the diagnosis, cure, treatment or prevention of diseases of man. A 80 proposes to amend the Revenue and Taxation Code so as to include the sales of medicines used as dietary supplements or adjuncts. A 129 proposes to amend the Revenue and Taxation Code by exempting from the sales tax the sale of medicines and drugs used in the diagnosis, cure, mitigation, treatment or prevention of disease in man, but not including any instrument or apparatus. A 152 proposes the appropriation of \$2,000,000 to the regents of the University of California to be expended for the erection and equipment of a hospital to be maintained and supported by the regents in conjunction with the medical school of the University of California. A 227 proposes to amend the law relative to the liability of innkeepers so as to include hospitals by providing that a hospital shall be liable for losses of or injuries to personal property belonging to patients to the same degree as would a depository for hire and providing further that if the hospital keeps a fireproof safe and notifies the patient to that effect then it is not liable for loss or damage to the personal property of a patient except so far as the acts of the hospital contribute thereto. A 230 proposes to authorize payments, out of the general funds of a city, city and county, or county of a physician's fee for issuing a food certificate to any person needing more than the ration thereof might provide. A 292 proposes to amend the state labor code by prohibiting an employer or insurance company writing compensation insurance from contracting with any physician, hospital or other person for the medical or surgical care or hospitalization of any injured person on the basis of such physician, hospital or other person receiving a percentage of the gross premiums collected by such insurance company or on the basis of any percentage of such employer's payroll or on the basis of any fixed charges which are less than the reasonable value of such services as fixed by rates adopted by the industrial accident commission. The bill would further prohibit a physician, hospital or other person from paying over to an employer or insurance carrier any rebate for sums received for the medical or surgical care or hospitalization of any injured employee. A 326 proposes to amend the Business and Professions Code relating to the practice of nursing by exempting therefrom the performance of certain services in case of an individual emergency and during a national emergency arising out of war or during an epidemic or other public disaster. A 327 proposes to amend the health and safety code regulating the licensing of clinics, dispensaries and maternity hospitals by exempting from such regulation a hospital corporation organized and operated exclusively for charitable purposes. A 328 proposes an amendment to the civil code which would create a lien in favor of doctors and hospitals for reasonable charges for hospital care, treatment and maintenance

of an injured person including drug supplies and x-ray and laboratory services on any recovery of any sum had or collected by such injured person whether by judgment or by settlement not to exceed however 50 per cent of such recovery. The proposal then sets forth certain notice requirements which the hospital or physician must give and provides a penalty against any person making payment or settlement or a claim without paying the amount covered by the lien. These provisions would not be applicable to claims arising under the workmen's compensation act, claims for wrongful death or negligent injury to a minor or claims for wrongful death to an adult or minor leaving a husband, wife or children. A 329 proposes to amend the law relating to medical and hospital care to indigents by prohibiting the board of supervisors from letting the care, maintenance or attendance of such indigent sick or dependent poor by contract to any person except that in cases of unusual difficulty or which require treatment or the use of facilities not immediately available in the county and in cases of emergency the board may secure by contract hospital care within or without the county, including medical, surgical x-ray, laboratory, nursing and general hospital service at a cost not exceeding the fair and reasonable value thereof in either a private or a state supported institution. A 334 proposes to amend the Business and Professions Code relating to the practice of chiropody by redefining chiropody to mean the diagnosis, medical, surgical, mechanical, manipulative and electrical treatment of the human foot and leg. The "and leg" is new and is substituted for the words "including the non-surgical treatment of the muscles and tendons of the leg governing the functions of the feet." A 335 proposes to amend the health and safety code by including a chiropodist in the class of persons who may purchase hypodermic syringes or hypodermic needles or may sign an authorization for such purpose.

Colorado

Bill Introduced—S 1 proposes to amend the law concerning vital statistics by making it the duty of the attending physician or midwife to file a certificate of birth within three days after the birth has occurred and setting forth the contents of such certificate.

Delaware

Bill Introduced—Senate substitute for S 7 proposes the enactment of a premarital physical examination law. Each applicant desiring to be married would be required to produce a certificate from a physician licensed by the Medical Council of Delaware or a nonresident licensed physician provided the qualifications of the said nonresident physician are equivalent to those required for license by the Medical Council of Delaware, certifying that he had undergone a thorough physical examination including a standard serologic test and a darkfield test, if indicated and stating that in the opinion of the physician the applicant is not infected with syphilis in a communicable stage. The total fee to be paid to any physician by the applicant shall not exceed the sum of \$2.50 over and above the fee charged by the laboratory and the required serologic test may be performed by the Delaware State Board of Health Laboratory or at a laboratory approved for this purpose by the executive secretary of the Delaware State Board of Health.

Georgia

Bill Introduced—H 25 proposes the creation of a board of naturopathic examiners to define and regulate the practice of naturopathy. The practice of naturopathy is defined as the science of treating the human body by use of natural methods and shall include the following therapeutic measures: hydrotherapy, psychotherapy, phytotherapy, mechanotherapy, phototherapy, thermotherapy, electrotherapy, biochemistry and embracing such practices as massage, mineral thermal, electrical and vapor baths, external application and dietetics. The proposal would exempt from the operation of its terms persons now authorized or hereafter authorized to practice medicine or surgery, chiropractic, osteopathy and chiropody as well as persons engaged in the practice of naturopathy in Georgia at the time of the passage of the bill who were so engaged for at least one year and who were graduates of an accredited naturopathic school. The proposed bill would further authorize naturopaths to use narcotics for the relief of pain and would provide that

naturopaths licensed under the act should observe and be subject to all state, county and municipal regulations in regard to the control of contagious and infectious diseases, with equal rights to use the facilities of the state board of health and to report all births and deaths and to any and all other rights pertaining to the public health in the same manner as is required of other practitioners of the healing arts

Idaho

Bill Introduced—H 24 proposes the enactment of a prenatal examination law. The proposal would require every licensed physician attending a pregnant woman, at the first examination or within fifteen days thereafter, to cause to be taken from such woman a blood sample to be submitted to a laboratory of the department of public health or some other approved laboratory for a standard serologic test for syphilis. In submitting such sample the physician shall specify whether or not it is for a prenatal test or a test following recent delivery. The bill also proposes that persons not permitted to take blood samples, but who do attend pregnant or recently delivered women, must within fifteen days of the first examination cause a sample of blood of such woman to be taken by a licensed physician and submitted as described.

Illinois

Bills Introduced—S 24 proposes to amend the pharmacy practice act by limiting to four hours in any one day the time during which any assistant pharmacist shall have the right to act as clerk or salesman in a drug store or pharmacy during the temporary absence of the registered pharmacist. H 8 proposes the creation of a "Cancer and Tumor Fund" to be used for the treatment of persons afflicted with cancer or tumor and the appointment by the county board of each county of a duly licensed physician familiar with cancer and tumor cases who shall maintain an office in some convenient place during the entire year for the purpose of examining applicants for the benefits of the fund.

Indiana

Bills Introduced—S 4 proposes the enactment of a law for the licensing and regulating of nursing homes, defined as any institution for care or treatment of three or more sick, infirm, convalescent, invalid, feeble-minded, mentally ill, incompetent, decrepit blind, disabled, injured, infected or chronically ill person, drug addict, dipsomaniac or inebriate, and for which care or treatment a charge is made. Exempted from the operation of the bill is treatment in a private household and in any hospital, home or institution conducted by or for the members of any religious body or denomination or regularly organized patriotic, fraternal or charitable organization. Among other things, the bill also proposes that it shall be unlawful to conduct a nursing home unless the treatment and care of inmates in such nursing home are in charge of a registered nurse. S 7 and H 29, although not identical bills propose to amend the workmen's compensation act in certain particulars. Among other things, the bill proposes that an employer shall provide the necessary first aid, medical and surgical services and all necessary medical and hospital services which are reasonably required to cure or relieve the effects of the injuries. Failure of the employee to accept such services would bar the receipt of compensation, and failure of the employer to furnish such services would authorize the employee to consult a physician of his own choice at the employer's expense. An examination of an employee made at the request of the employer shall be performed in the presence of a duly qualified physician or surgeon provided and paid for by the employee, if the employee so desires, and where a physician chosen by the employee is not present the physician engaged by the employer shall furnish the employee with a statement in writing of the conditions evidenced by such examination not later than forty-eight hours before any hearing in the matter is set. H 66 proposes the enactment of a law regulating the operation of plants for the cold storage of food in individual lockers. Among other things the bill proposes that all employees of such locker plants shall undergo a semi-annual health examination by a physician and requires the employer to keep such health certificates on file at all times. Furthermore the bill proposes to prohibit any person suffering from a communicable disease, including any communicable skin

disease or with infected wounds, and any person who is a "carrier" of a communicable disease from being employed in any capacity in such a locker plant. H 78 proposes the creation of a state board of natural therapeutic physicians to examine and license practitioners of natural therapeutics, such board to consist of six members, including two chiropractors, two naturopaths and two physiotherapists. The bill defines the practice of natural therapy as the diagnosis and treatment of human ailments, by manual and mechanical manipulation and adjusting of the spine and its appendages, the use of herbal remedies, cell salts, diet and the application of heat, cold, air, water, light, electricity, radiant energy and exercise in the treatment of disease injury or deformity. After passing the required examination a license shall be granted to practice the system or systems for which the applicant is qualified, and the license shall designate the system of natural therapeutics which licensee is permitted to practice. Finally the bill proposes to authorize licensees thereunder to sign death certificates and execute all legal documents with the same authority as members of any other school or system of healing and proposes to exempt from its operation persons lawfully carrying on their particular profession of healing under any valid existing act of the state, persons rendering gratuitous services in cases of emergency, persons who administer to or treat the sick or suffering by spiritual means or prayer and persons giving baths and massage.

Kansas

Bills Introduced—H 25 proposes the granting of temporary licenses to nurses now licensed as such, or who at one time have been licensed as such, outside the state if they are found qualified to practice as nurses in the state during the present war emergency period. Holders of such temporary licenses shall be subject to the same rules and regulations and restrictions as regular licensees. H 40 proposes to abolish the present state board of medical registration and examination and state board of osteopathic examination and registration to create a state board of physicians and surgeons registration and examination to be composed of physicians in good standing in their profession who shall have received the degree of doctor of medicine or doctor of osteopathy and to amend the medical practice act in certain particulars so as to include osteopaths under the same terms as physicians and surgeons. Licenses issued by this board would grant the right to practice medicine and surgery and would grant rights to osteopaths equal in every respect to those granted to physicians and surgeons.

Massachusetts

Bills Introduced—S 42 proposes the enactment of a law to regulate the sale of apparatus designed as aids to hearing by, among other things requiring that such sales be made only on prescription of a registered physician who is not in the employ of the seller. S 62 proposes to authorize the board of registration of nurses, for a period of six months following the taking effect of such proposal to register without examination any nurse who is a graduate of a training school for nurses satisfactory to the board and who has practiced nursing for a period of five years last preceding the effective date of the act. S 106 proposes to add a new section to the employment security act providing that payment of benefits shall be made for a period of four weeks prior to the date of birth or delivery of a child and for the four weeks next ensuing after the date of birth or delivery of a child. H 82 proposes a resolution to the federal manpower commission requesting that public mental hospitals in the state of Massachusetts be classified as a "war industry." H 87 proposes that before a hospital or sanatorium can be licensed or have its present license renewed it must present a certificate of approval of the egresses, the means of preventing the spread of fire and the apparatus for extinguishing fire issued by a building inspector of the department of public safety or, in the case of a hospital or sanatorium located in the city of Boston, by a building inspector of said city. H 88 proposes to amend the law licensing dispensaries or clinics so as to include dental clinics as well as those furnishing medical or surgical advice and treatment and proposes to exempt from the operation of such licensing requirements dental clinics conducted by a licensed maternity hospital. H 89 proposes to amend the

in licensing clinics and dispensaries by providing that the term "dispensary" shall not include a clinic conducted by a regularly licensed maternity hospital. H 94 proposes numerous amendments to the food and drug act to make it more nearly conform to the federal food, drug and cosmetic act. Among other things the proposed bill would provide that a drug sold at retail and containing aminopyrine, barbitalic acid, cinchophen, dinitrophenol sulfanilamide, or their derivatives, or any other drug which has been found by the department to be dangerous to health when used in the dosage, or with the required frequency or duration prescribed recommended or suggested in the labeling thereof, and so designated by it in a regulation adopted shall be misbranded unless it is dispensed on a written prescription signed by a member of the medical, dental or veterinary profession who is licensed by law to administer such drug, and its label bears the name and place of business of the seller, the serial number and date of such prescription and the name of such member of the medical dental or veterinary profession. It is further proposed that a drug dispensed on a written prescription signed by a member of the medical, dental or veterinary profession (except a drug sold in the course of the conduct of a business of selling drugs pursuant to diagnosis by mail) shall be exempt from the foregoing requirements if the person writing the prescription is licensed by law to administer such drug and if the drug bears a label containing the name and place of business of the seller, the serial number and date of such prescription and the name of such member of the medical, dental or veterinary profession. H 303 proposes that no health or accident policy which has been in force for a period of three or more years shall be canceled, annulled or renewal refused except for nonpayment of premium or assessment or for good cause shown.

Maryland

Bills Introduced—H 46 proposes to amend the workmen's compensation act by requiring the employer to provide medical, surgical or other attendance or treatment, nurse and hospital services, medicines, crutches, apparatus artificial hands, arms, feet and legs and also to repair or replace eyeglasses which are damaged or destroyed as the result of an accident during the course of the employment. H 53 proposes to amend the insurance code by exempting from the provisions thereof any policy or contract granting solely and exclusively hospitalization insurance. The present law exempts any policy or contract issued by a non-profit association. H 59 proposes to amend the workmen's compensation act by redefining the terms "injury," "personal injury" and "accidental personal injury" to include all hernias arising out of and in the course of employment. H 63 proposes to amend the workmen's compensation act by increasing the compensation to employees suffering from neither total permanent or total temporary disability. H 80 proposes to amend the workmen's compensation act by increasing the compensation for total loss of hearing of both ears. S 84 proposes to amend the medical practice act by eliminating the proviso that two courses of medical lectures, both of which shall be either begun or completed within the same calendar year, shall not satisfy the aforementioned requirements. This amendment is apparently for the purpose of enabling graduates of accelerated medical courses to obtain licensure in Maryland. S 92 proposes the creation by the state board of health of two institutions for the treatment of needy persons requiring medical, nursing or custodial care by reason of chronic illness or infirmity. Admission to such institution shall be on the basis of a statement by a physician and shall be limited to patients who are not suffering from tuberculosis in a transmissible form mental disease of the type requiring care in a mental hospital, an orthopedic disease of a type admissible to the special orthopedic hospitals and who are under the age of 16 years. H 76 proposes to repeal that section of the licensing law providing that no county city or other political subdivision of the state shall require a license to transact any business or occupation which is required to obtain a state license.

Michigan

Bills Introduced—S 9 proposes to amend sections 12883 to 12888 of the Compiled Laws of 1929 providing for free medical and surgical care at the University of Michigan Hospital for

certain dependent children. S 15 proposes the abolition of the office of coroner and the creation of a medical examiner system. The state medical examiner shall be a physician licensed to practice medicine within the state of Michigan and shall possess special training in pathology and the investigation of violent deaths. The board of supervisors of each county in the state would be required to appoint a county medical examiner who shall be a physician licensed to practice medicine within the state and a resident of the county or an adjoining county. The proposal then sets forth the duties of the state medical examiner and the various county medical examiners, among which is the duty, on the part of the state medical examiner, to organize and conduct a laboratory to facilitate the carrying out of the purposes of the act. H 40 proposes to amend the existing premarital examination law by providing that no such examination shall be required of persons serving in the armed forces of the United States during the continuation of the war.

Nebraska

Bills Introduced—Bill No 40 proposes the requirement of a premarital examination by each applicant for a marriage license. The necessary certificate shall be signed by a duly qualified physician licensed to practice medicine and surgery in any state or United States territory and shall certify that the applicant is not infected with syphilis in a communicable stage. Bill No 41 proposes the enactment of a premarital examination law. This bill would require every physician attending a pregnant woman to take a sample of blood of such woman at the first examination and submit such sample to an approved laboratory for a standard serologic test for syphilis. In reporting every birth and stillbirth, physicians and others required to make such reports shall state on the certificate whether a blood test for syphilis has been made on a specimen of blood taken from the woman who bore the child, but the birth certificate shall not show the result of such test.

New Jersey

Bill Introduced—A 41 proposes to amend the medical practice act by repealing chapter 115 of the laws of 1939. That law was a general amendment to the medical practice act making uniform the requirements for a license for all persons who practice any branch of medicine or surgery or use any method of treatment of human ailment disease, pain, injury, deformity mental or physical condition except certain enumerated classes of persons already licensed within the state.

Ohio

Bills Introduced—S 13 proposes to amend the law relative to privileged communications by providing that a physician may testify by express consent of the patient or if the patient is dead by express consent of the executor or administrator of the patient and by providing further that if the executor or administrator of a patient voluntarily testifies the physician may then be compelled to testify on the same subject. S 17 proposes to exempt from the operation of the sales tax the sale of drugs or medicine compounded, prepared or sold in accordance with or under a prescription issued by a licensed practitioner of medicine.

Rhode Island

Bill Introduced—H 533 proposes the creation of a special commission, to be known as the Special Rhode Island Public Health Laws Survey Commission to make a comprehensive reexamination and survey of the public health laws of the state and municipalities thereof and to make recommendations for complete modernization of those laws in keeping with the most recent innovations and tried practices of other states. Such recommendations must be made in legislative form not later than April 12, 1943.

South Carolina

Bill Passed—S 17 passed the Senate on January 21. This bill proposes to eliminate from the educational requirements of physicians stated in the medical practice act the requirement that the necessary four full courses of lectures of at least twenty-six weeks each must have been given in four different years. The purpose of this proposal apparently is to enable graduates of accelerated medical courses to obtain licensure in South Carolina.

Medical News

(PHYSICIANS WILL CONFERR A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

DISTRICT OF COLUMBIA

Society Aids in Low Cost Care for Federal Women Workers—The Medical Society of the District of Columbia is cooperating with the U. S. Public Health Service in providing low cost medical care to the women who will occupy the four new dormitories scheduled for early completion by the government according to the *Washington Daily News* January 20. Under the program private physicians still will operate independently and bill their patients separately but will base their fees on a special low priced schedule agreed on for workers making less than \$1620. Infirmarys will be set up in each of the four dormitories in charge of a chief nurse and an assistant to be paid out of public funds. They will give girls free infirmary care for minor illnesses and will present each girl with a medical society panel list of physicians from which to choose should she require care. The medical societies of Prince Georges and Arlington counties and the Medical and Chirurgical Faculty of Maryland are also cooperating in the project. Office space will be provided for physicians at each dormitory. Arlington Farms with six residence halls accommodating about 600 women will have a sixty bed infirmary, West Potomac Park with three halls a sixty bed infirmary, Langston Stadium for Negro girls a 12 bed infirmary and Suitland will have accommodations for six beds. The plan was developed by the public health service which anticipates that the infirmaries will take some of the load off hospitals, it was stated.

ILLINOIS

Suits Against State Officials Dismissed—The U. S. Circuit Court of Appeals ruled on Dec. 15, 1942 that private citizens may not sue state officials to recover damages alleged to have been sustained through official acts, newspapers reported. The decision was handed down in suits against A. L. Bowen, Springfield former state director of public welfare, Mrs. Blanche Fritz, former assistant director, Dr. Albert C. Baxter, Springfield former state director of public health and Dr. Ralph T. Hinton Pryson, former superintendent of the Manteno State Hospital, Manteno. The suits grew out of a typhoid epidemic at the hospital in 1939, when a number of persons died.

Chicago

Memorial Service for Physician Who Died in Military Service—The Chicago Medical Society sponsored a memorial service in the Sauganash Community Church January 10 for Major Lemuel Edward Day, M. C., U. S. Army, who 'died in a New Guinea field hospital December 23, 1942, two days after he had won the silver star for heroism in a bombing raid on his hospital.' Major Day was a first lieutenant in the field artillery in World War I. He joined the army again last June.

Branch Meetings—Dr. Dallas B. Phemister will address the North Shore Branch of the Chicago Medical Society February 2 on 'Prevention and Treatment of Surgical Shock.' At a meeting of the North Suburban Branch, January 11, Drs. Paul S. Rhoads and Samuel J. Lang, Evanston, Ill. discussed 'Nonspecific Pneumonia: Report of 100 Cases and Adrenal Cortical Insufficiency and Its Treatment' respectively. At a joint meeting of the South Chicago and South Side branches January 14 the speakers were Drs. Daniel H. Levinthal on 'Surgery of Derangements of the Knee Joint' and Sidney A. Portis 'Modern Treatment of Liver Disease.' The Northwest Branch was addressed January 15 by Drs. Frank F. Maple and Charles H. Pluifer on 'Bleeding in the Third Trimester' and 'Procurement and Assignment for Physicians' respectively. The Douglas Park Branch devoted its meeting January 19 to a showing of a new motion picture film on peptic ulcer. The Jackson Park Branch was addressed on January 21 by Dr. M. Edward Davis on 'The Therapeutic Role of the Estrogens in Gynecologic Practice.' John F. Svoboda, D.D.S., spoke on 'Oral Lesions of Interest to the General Practitioner' at a meeting of the West Side Branch January 21. A joint meeting of the Englewood and Stock Yards branches was addressed January 21 by Dr. Karl A. Meyer on 'Surgery of the Colon Exclusive of the Rectum.'

The Aux Plumes Branch was addressed, January 22, by Dr. Harold O. Jones on 'Office Gynecology.' Dr. Italo F. Volini spoke on 'Pneumonia—Typical and Atypical Types,' before the Calumet Branch, January 22.

INDIANA

Examination of Applicants for Reciprocity Suspended—At a meeting January 12 the Indiana State Board of Medical Registration and Examination passed a resolution to suspend the practical examination for reciprocal applicants for the duration. It was also decided to suspend the requirement of one year's practice in the original licensing state for reciprocal applicants. The board also changed the regulation for graduates located outside the United States and possessions to read 'outside of the United States and its possessions, and outside the Dominion of Canada for the duration.'

Dr. Stayton Retires as Editor of Bulletin—Dr. Chester A. Stayton, Indianapolis, has retired as editor in chief of the Indianapolis Medical Society Bulletin, a position he had held since he established the bulletin in its present form in June 1931. Mr. Russell Campbell, secretary to Mayor Sullivan of Indianapolis, is the new editor in chief on a part time basis. Prior to its establishment in its present form the bulletin was published weekly as a post card. Dr. Stayton, who was then secretary of the society, continued the new bulletin with the volume number that had been carried by this weekly card.

Physician Recommended for Navy Cross—Dr. Don M. Matton, Terre Haute lieutenant (j. g.), M. C., U. S. Navy, has been recommended for the Navy Cross and cited for decorations by both navy and army commands as a result of service rendered during the invasion of French Morocco, according to the state medical journal. Dr. Matton entered the service on July 16, 1942 and was first assigned to duty with the U. S. Marine Corps at Parris Island, S. C. Later he was transferred to the amphibious forces of the navy and served with the naval medical units on the African beaches in the vicinity of Casablanca during the invasion which began on November 7.

MARYLAND

One Case of Smallpox Breaks Twelve Year Record—The occurrence of a mild case of smallpox in St. Mary's County has broken a record of twelve years without a report of the disease. The case was traced to an Amish minister who had visited the Amish area in Pennsylvania where an outbreak had occurred in December (THE JOURNAL, January 2, page 61). The minister had visited Charles and St. Mary's counties. Vaccination of all known contacts was under way within one hour after the information was received. All those known to have been exposed to the disease were vaccinated except one man who was not vaccinated until December 28. It was this man who developed a mild case of smallpox. Regular vaccination clinics are being conducted in localities where contacts and cases have come into Maryland from the parts of Pennsylvania where the disease had occurred.

Premedical Study Reduced at University of Maryland—The faculty of the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, has agreed to reduce the period of premedical study for admission to two academic or scholastic years, or their equivalent consisting of not less than sixty semester hours provided the minimum number of semester hours of instruction in the prescribed basic subjects for a premedical education is included exclusive of physical education and military science in an approved college of arts and sciences. This is in conformity with the recommendations of the Association of American Medical Colleges and the Council on Medical Education and Hospitals of the American Medical Association. The reductions in admission requirements are to continue in force until further notice. The decision was made following the adoption of resolutions recommending the action by the Association of American Medical Colleges and the Council on Medical Education and Hospitals of the American Medical Association.

Dr. Streeter Honored—To mark his many years of service to the Carnegie Institution of Washington, volume 30 of the Contributions to Embryology which appeared Dec. 31, 1942 was dedicated to Dr. George L. Streeter, Baltimore, who was director of the department of embryology at the institution from 1918 to 1940 and chairman of the division of animal biology from 1935 to 1940 when he became research associate. The tribute also recognizes the work of Dr. Streeter in serving as editor of the volumes 8 to 29 during the period 1917 to 1940. Science reports that it is customary, when such an achievement is to be honored, to assemble a testimonial volume of especially written articles. Dr. Streeter's colleagues chose, however, to convey their tribute by means of a regular volume.

of the series prepared in the usual course of scientific research thinking that in this way they might best call attention to the fact that the whole series is a testimonial to Dr Steeter. This volume represents workers of ten laboratories in three continents. Most of the investigations were carried out in the Carnegie Embryological Laboratory and all except one made use of its collections or other facilities. It is dedicated to Dr Streeter in the name not only of the present contributors but of all those investigators now scattered over the Americas Europe and Asia, many of them inaccessible or distracted by reason of the war, who have worked in this laboratory and published their results under his editorship. The volume also contains an article prepared by Dr Streeter testifying to his eminence as investigator as well as editor. Dr Streeter was born in Johnstown N Y. He graduated at Columbia University College of Physicians and Surgeons New York, in 1899. He was demonstrator in anatomy of the nervous system at Albany Medical College 1901-1902 later he served as assistant and instructor in anatomy at Johns Hopkins University School of Medicine Baltimore, and assistant professor of anatomy at the Wistar Institute of Anatomy and Biology at the University of Pennsylvania, Philadelphia. He was professor of anatomy and director of the anatomy laboratory at the University of Michigan Medical School, Ann Arbor, from 1907 to 1914 when he went to the Carnegie Institution as research associate. A member of many national scientific societies, Dr Streeter was president of the American Association of Anatomists in 1926. His research has been concerned with human embryology development of the central nervous system, the internal ear and experimental biology.

MICHIGAN

Program to Conserve Hearing—The Michigan Department of Health and the state department of public instruction are cooperating in a new program especially planned to help hard of hearing children. The program aims to discover actual and potentially hard of hearing children. Medical attention will be arranged and educational opportunities offered for both the children and the parents. Audiometric hearing tests will be given by the state department of health.

District Units for Industrial Hygiene—Two new district offices have been set up by the state bureau of industrial hygiene bringing the total of such district units to five. One new unit is located in the Kalamazoo City-County Department of Health, with facilities for Kalamazoo Van Buren Berrien Cass and St Joseph counties. The second unit in the Washtenaw County Health Department in Ann Arbor serves Washtenaw, Jackson Hillsdale and Lenawee counties. Other units are located in Grand Rapids Saginaw and Pontiac.

Victory Day Clinic—The staff of Mount Carmel Mercy Hospital Detroit held a "victory day clinic" January 27. Participating in the clinic were

Drs Harold L. Morris and Samuel A. Flaherty Detroit Urology
Dr. William L. Bendel Monroe La. Pelvic Inflammatory Disease
Treatment and Its Course
Dr. Carl E. Badgley Ann Arbor Treatment of Colles Fracture
Dr. William Reid Morris on Boston Certain Aspects of the Problems of Castric Surgery
Dr. Charles F. McKhann Ann Arbor Neonatal Care
Dr. Edgar H. Norri Detroit (subject not announced)
Dr. Albert C. Furstenberg Ann Arbor Diseases of the Salivary Gland
Dr. Fay A. Le Fevre Cleveland Treatment of Coronary Heart Disease
Dr. Irving W. Potter Buffalo Why We Do Podalic Version

NEW YORK

The Lucien Howe Prize—The Medical Society of the State of New York announces that all essays for the Lucien Howe Prize must be received by the chairman of the committee on prize essays of the society, Dr. Charles G. Heyd, 292 Madison Avenue New York, not later than March 1. One hundred dollars will be presented for the best original contribution on some branch of surgery preferably ophthalmology during the annual meeting of the medical society in Buffalo in May.

Plasma Education Program—A graduate medical education program in the indications for and technics of using blood plasma is being prepared by the state medical society. Office of Civilian Defense and the state department of health and will be launched soon through the medical society's committee on public health and education. Plans are being patterned after the recent method of handling and treatment at the Massachusetts General and Boston City hospitals after the Coconut Grove disaster. According to *Health News* one of the hospitals was fortunate in having not only a complete burn unit organized in advance of the disaster but also a trained technical team. At the other hospital a similar unit was in process of organization and, although not completed at the time of the fire, the progress that had been made was clearly

reflected in the expeditious manner with which it was possible to care for the tremendous number of injured persons in a very short time. Dr. Earle B. Mahoney who is in charge of the blood plasma unit at Strong Memorial Hospital Rochester and who is serving as consultant to the state department of health, and Dr. Edward S. Rogers Albany assistant commissioner for medical administration on the department's staff studied the Boston situation shortly after the disaster.

Dr. Calkins Dies—Gary A. Calkins Sc.D. professor emeritus of protozoology at Columbia University New York died in Scarsdale January 4 aged 73. After graduating in 1890 at the Massachusetts Institute of Technology Boston Dr. Calkins was for the next three years assistant biologist to the Massachusetts Department of Public Health and a lecturer in biology at the institute. In 1894 he was made a tutor in zoology in the newly organized zoology department at Columbia in 1903 assistant professor of zoology and in 1904 a full professor. Three years later he became the first professor of protozoology retiring in 1939 as professor emeritus. From 1903 to 1908 he was biologist for the New York State Cancer Laboratory Buffalo and since 1937 had been a member of the Columbia Consulting Board for Cancer Research. During his many years at Columbia Dr. Calkins had also taught parasitology and gave the invertebrate half of the general undergraduate course in biology. From 1928 to 1931 he was executive officer of the department of zoology at Columbia and in 1935 while on sabbatical leave delivered a series of lectures at the School of Tropical Medicine of Puerto Rico University San Juan. Dr. Calkins was a member of numerous scientific organizations and from 1913 to 1914 was president of the American Society for the Control of Cancer and from 1919 to 1921 of the Society of Experimental Biology and Medicine.

New York City

Public Welfare Commissioner Killed in Airplane Crash—William Hodson LL.B. commissioner of public welfare who had been carrying out a mission for Herbert H. Lehman, LL.D. federal director of foreign relief and rehabilitation, was killed in an airplane accident in Paramaribo Dutch Guiana January 15. Mr. Hodson recently completed his ninth year of service as commissioner of public welfare and had been granted a two months leave of absence to undertake a mission for former Governor Lehman.

Bacteriologist Dies—Frederick Dixon Chester bacteriologist and chemist died at his home in the Bronx January 1, aged 82. Dr. Chester was born in Santo Domingo Haiti in 1861. He received his M.S. degree at Cornell University, Ithaca N.Y. in 1885. He had served as professor of geology and botany at Delaware College bacteriologist and mycologist, Experimental Station Delaware, and director of the Delaware State Bacteriological Laboratory. He was a consulting chemist and bacteriologist from 1907 to 1924 when he became the chief chemist of the Strickpole Carbon Company in Pennsylvania a position he left in 1930 to become director of research of the Technical Sales Corporation.

Course in Industrial Medicine and Surgery—Columbia University announces a postgraduate course in industrial medicine and surgery to be held February 1-15. Members of the faculty of medicine the De Lamar Institute of Public Health and visiting lecturers will conduct the series. Among the speakers will be

Dr. Melver Woods Organization of an Industrial Medical Service
Dr. John J. Wittmer Industrial Absenteeism
Dr. Leroy C. Gardner Struma Lake N.Y. Silicosis Asbestosis and Other Dust Disease
Dr. George M. Mackie Industrial Dermatitis
Frederick B. Flinn Ph.D. Poisoning Due to Metals Other Than Lead
Dr. Wolfgang F. von Oettingen Bethesda Md. Poisoning Due to Crises
Helmuth H. Schrentz Ph.D. Pittsburgh Poisoning Due to Hydrocarbons

Report Shows Increase in Venereal Disease—A serious rise in venereal disease was noted for 1942 according to the annual report of the city health department. For the first eleven months of the year there were 28,068 cases of syphilis recorded, an increase of 13 per cent over the corresponding period of 1941. A total of 11,208 cases of gonorrhea was reported with the number of unreported cases thought to be many times greater according to the New York Times. Neither venereal disease nor any other vital statistics of service men on duty are included in the city reports. The birth rate was 17.4 per thousand estimated population in 1942 the highest since 1930 when it reached 17.7. An all time low was noted in the city's infant mortality rate of 25.8 for 1,000 live births. The general death rate was 10 per thousand of estimated population. The rate for tuberculosis was 46.3 per hundred thousand and that for pneumonia 39.1. Seven deaths from diphtheria were recorded as against ten in 1941. 90 cases

and nine deaths from infantile paralysis, and 437 from appendicitis, giving a new low rate from this cause of 58 per hundred thousand. Accidents caused 3,643 deaths, accounting for a rate of 48.1 per hundred thousand.

NORTH CAROLINA

Report of Society—The Buncombe County Medical Society in a report of its activities for the past year announces its decision to discontinue publication of its monthly bulletin and to hold only one meeting a month for the duration of the war. Among other activities, the society aided in advancing the development of a hospital for Negroes at Asheville, organized a blood plasma bank, and turned its management over to the city health department. It sponsored weekly radio talks by members. Thirty-six members of the society, being just one third of the active membership, are now serving with the armed forces of the United States.

OHIO

Department of Physical Medicine Created at State University—The establishment of a department of physical medicine at the Ohio State University, Columbus, with quarters on the first floor of University Hospital has been announced. Dr. David E. Jones, clinical assistant in orthopedic surgery, University of Louisville School of Medicine, Louisville, Ky., has been placed in charge of the new department.

Industrial Health Program Formulated—Recommendations for an active industrial health program in Ohio were recently approved. They were submitted in a report of the newly formed committee on industrial health of the state medical association and are to form sound local educational programs on industrial health designed to curtail absenteeism of workers, especially in war industries, because of sickness and injury, to eliminate health hazards in plants, to educate workers and their families to keep themselves in good health, to encourage good health and medical services for employees, and to provide educational opportunities for members of the medical profession on matters of industrial health and the care of those disabled as a result of employment. The establishment of state and local organizations within the medical profession to carry out these objectives was also recommended. Dr. Barney J. Hein, Toledo, is chairman of the new committee on industrial health and other members are Drs. David W. Heusinkveld, Cincinnati, Herbert M. Platter, Columbus, George F. Sykes, Cleveland, Ernest O. Swartz, Cincinnati, Ralph M. Watkins, Cleveland, Orville J. Walker, Youngstown, Carl A. Wilzbach, Cincinnati, and the president, president-elect and past president of the state medical society, ex officio.

RHODE ISLAND

Midwinter Meeting of the State Medical Society—The Rhode Island Medical Society will hold a special midwinter meeting at the Medical Library, Providence, February 4. Dr. James E. Paulin, Atlanta, Ga., President-Elect of the American Medical Association will discuss "The Contribution of the Physician in the Present Crisis." Other speakers will be Drs. James C. McCann, Worcester, Mass., and Herman C. Pitts, Providence, on "Prepaid Medical Care and the National Outlook" and "The Rhode Island Cash Sickness Act" respectively.

TEXAS

Hospital Group Plans War Conference—The Texas Hospital Association will conduct a war conference February 18-19, at the Hotel Texas, Fort Worth. Among the speakers will be James A. Hamilton, New Haven, Conn., president of the American Hospital Association. Other speakers will include Major James H. Stephenson, U. S. Public Health Service on "Civilian Defense in Hospitals", F. Hazen Dick, Louisville, Ky., and Everett W. Jones, B.S.E., Washington, D. C., "Hospital Purchasing in Wartime," and Russell L. Dicks, Dallas, "Psychosomatic Medicine and Its Implications for the Treatment of the Patient." Other groups meeting at the same time are the Association of Records Librarians of Texas, Texas Association of Nurse Anesthetists and the Texas Association of Hospital Accountants.

VIRGINIA

Courses on Industrial and Military Medicine—The state medical society is preparing a series of graduate courses on industrial and military medicine to be given in various sections of Virginia. The program will provide for afternoon, dinner and evening meetings in each of five centers comprising a circuit of a week. According to present plans the courses will begin the latter part of February or early in March with from three to five speakers on each program.

WISCONSIN

Personal—Dr. Edwin Hall Jorris, Madison, supervisor of local health services and director of the division of tuberculosis control of the Wisconsin State Board of Health has been commissioned a lieutenant commander in the medical corps of the U. S. Naval Reserve.

Information Please Program on Therapeutics—The Medical Society of Milwaukee County devoted its meeting, January 8, to an "information please" program. Therapeutics was the theme of the program, and Drs. Edward H. Rynearson, Rochester, Minn., Ovid O. Meyer, Madison, Francis D. Murphy, Frederick W. Madison and Theodore L. Squier, Milwaukee, constituted the board of experts.

Dr. Harper Retires After Thirty-Nine Years as Health Officer—Dr. Cornelius A. Harper, Madison, retired on January 28 as state health officer, a position he has held since April 1, 1904. He has been a member of the board since February 1901. Dr. Carl N. Neupert, Madison, who has been assistant state health officer for six years, has been named secretary to the board of health and state health officer. Dr. Harper has been named medical specialist in public health to the state board. He graduated at the Columbian University Medical Department, Washington, D. C., in 1893.

GENERAL

Women Over Thirty Urged to Have More Babies—According to statisticians of the Metropolitan Life Insurance Company, American women of 30 and over must have more babies if the present high birth rate is to be maintained. The withdrawal of large numbers of men for military service will result in a decrease in births among younger women, it is pointed out. In the case of women of ages 30 and over, the contribution to total annual births was smaller at the end of the last two decades than at the beginning. In 1920 their contribution was 35 per cent of the total births as against 29 per cent of the total babies born in 1940. Most married women of these ages already have children so that their hands are for the most part, still out of the classes called for military service, it was stated. In addition, thousands of these families are now in a better economic position than ever to rear more children.

New Motion Picture on Sulfonamide Therapy—A new motion picture on sulfonamide therapy was recently released by Lederle Laboratories, Inc., and is available for bookings without charge to medical groups. The film was prepared by and under the supervision of Drs. Norman H. Plummer, assistant professor of clinical medicine at Cornell University Medical College, New York, and Charles H. Wheeler, assistant in pharmacy (therapeutics) at Cornell. The film reviews the development of the sulfonamides from 1908 to the present time. The chemical aspects are shown in scenes taken at the sulfonamide research division of the Lederle Laboratories, and therapeutic applications are revealed in scenes taken at the New York Hospital. By special arrangement, Drs. Edward F. Roberts, New York, and Florian E. Schmidt, Chicago, will present the film with comments, or the film may be borrowed by medical societies or hospital staffs.

Mr. Fieser's Work Expanded for Red Cross—Mr. James L. Fieser, Washington, D. C., who has been vice chairman in charge of domestic operations of the American Red Cross since 1922, has become vice chairman at large in accordance with organizational changes made to meet the expanding activities of the national group. Mr. Fieser will report to the chairman and will assist the chairman and the operating departments and services in relations with the many national organizations which are becoming increasingly important to the Red Cross. He will assist with the War Fund Campaign, will be available for such special assignments and for attendance at such meetings as may be requested by the chairman, and will be of assistance to the operating departments and services. The department of domestic operations will report to the executive vice chairman, Mr. Lloyd B. Wilson, Washington, D. C., who will assume this responsibility in addition to his other duties.

Walter Reed Medals Presented—The American Society of Tropical Medicine presented two Walter Reed medals during its recent annual meeting in Richmond in November. One was presented to the United States of Brazil through its minister of education and public health, Dr. Gustavo Capanema, Rio de Janeiro, for outstanding work in eradicating Anopheles gambiae from Brazil. In the absence of Dr. Papanema, Dr. Mario Kroeff, Rio de Janeiro, director of National Cancer Service, received the award. The second medal was presented posthumously to Dr. Carlos J. Finlay for pioneer work in yellow fever. Dr. Finlay's son, Dr. Carlos E. Finlay, was to

have received the medal, but because of his illness it was received by Dr Domingo F Ramos director of the Finlay Institute Havana. Dr Wilbur A Sawyer, N Y, was chosen president elect of the American Society for Tropical Medicine and Dr N Paul Hudson Columbus Ohio was installed as president. Rear Admiral Charles S Stephenson, M C U S Navy, is vice president, Col Charles F Craig San Antonio Texas editor, and Dr Joseph S D'Antoni, New Orleans secretary-treasurer.

Grants Available by Ella Sachs Plotz Foundation—The Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation announces that, during the present great need for funds, forthcoming grants will be given in the sciences closely related to medicine without reference to special fields, a policy somewhat neglected in the past. The maximum size of grants will usually be less than \$500. Applications for grants to be held during the year 1943-1944 must be received by the executive committee before April 1943. There are no formal application blanks but letters asking for aid must state definitely the qualifications of the investigator, an accurate description of the research, the size of the grant requested and the specific use of the money to be expended. Applicants should also state whether or not they have approached other foundations for financial assistance. Applications should be sent to Dr Joseph C Aub, Massachusetts General Hospital, Fruit Street, Boston. In its nineteenth annual report the Ella Sachs Plotz Foundation stated that twenty-six grants were made during the past year, one being a continued annual grant. Forty-four applications for grants were received by the trustees, thirty-six of which came from the United States, the other eight coming from six different countries in Europe, Asia and North and South America. The foundation has distributed four hundred and fifty-five grants to scientists throughout the world during its nineteen years' existence.

Prize for Research on Problems of Alcohol—The Research Council on Problems of Alcohol has announced the establishment of a \$1000 award for outstanding research on alcoholism during 1943. The research must contribute new knowledge in some branch of medicine, biology or sociology important to the understanding or prevention or treatment of alcoholism. The project may have been inaugurated at any time in the past or during the year, provided that a substantial part of the work is carried on during the year, that it is developed to a point at which significant conclusions are possible before the end of the year and that a report on the work has not been previously announced and described before a scientific body or previously published. It is desirable, but not necessary that those planning to work for the award send to the council before March 1 a statement of such intention. If the council receives such information it can be helpful in the prevention of undesirable duplication of effort. If a research project is conceived and inaugurated later in the year, a statement of intention may be sent to the council at a later date. A report on the work and resulting conclusions must be submitted to the Research Council on Problems of Alcohol on or before Feb 15, 1944. The council will provide an outline for use in the preparation of reports. The award will be in cash and will be given to an individual scientist whose work is judged sufficiently significant to merit the award. The committee of award will consist of five persons—an officer of the American Association for the Advancement of Science and four representatives of the scientific committee of the Research Council on Problems of Alcohol. Any scientist in the United States Canada or Latin America is eligible for the award. The council will send on request to any scientist an outline of basic policies governing its research program lists of council studies (completed, under way and contemplated), and information regarding the studies of other agencies. Scientists planning to do research in connection with the award may send a statement of intention to the director Research Council on Problems of Alcohol, 111 Pondfield Road West Bronxville, N Y.

LATIN AMERICA

Personal—Drs Jorge Milan Gutierrez Mexico, was recently chosen president of the Sociedad Mexicana a Dermatologia of Mexico City, Pedro Daniel Martinez was elected secretary and Robert Nunez Andrade treasurer.

Medical Congress Marks Anniversary Centennial—The first National Congress of Medicine was held at the University of Chile, Nov 17-21 1942 under the direction of the faculty of biology and medical sciences of the university as a part of the centennial celebration of the university. The University of Chile was founded on Nov 19 1842. According to the *Revista Medica de Chile* October 1942 it is deplored that the world conflict restricted the participation of medical men of North America.

FOREIGN

Royal College of Physicians—The annual meeting of the Royal College of Physicians of Edinburgh was held Dec 3 1942. Dr Charles McNeil was reelected president and Dr Lewis H F Thatcher, Alexander Murray Drennan Andrew Fergus Hewat David M Lyon Andrew Graham Ritchie and Andrew Rae Gilchrist were elected to form the council of the college for the ensuing year. Dr Hewat was nominated vice president.

Scientists Honored—Sir Robert Robinson D Sc, Oxford, authority on organic chemistry recently received the Copley Medal of the Royal Society. Sir William Wilson Jameson formerly dean of the London School of Hygiene and Tropical Medicine and now chief medical officer to the Ministry of Health and the Board of Education, London received the Buchanan Medal for "administrative and constructive work" of outstanding merit in the service of hygienic science. Other awards of the society went to Prof Walter A Haworth D Sc Birmingham for his work in organic chemistry and Dr William W C Topley London for his studies in bacteriology. The awards were announced by Sir Henry H Dile CBE fullerton professor and director of the laboratories of the Royal Institution London and president of the Royal Society, in an address commemorating the three hundredth anniversary of the birth of Isaac Newton.—Dr Alfred Vogt professor of ophthalmology at the University of Zurich Switzerland, since 1923 has been presented with the Gullstrand Medal by the Swedish Medical Society of Stockholm. The medal is awarded every ten years to an eminent ophthalmologist. **Science reports**—Professor Von H Mooser director of the Institute of Hygiene of the University of Zurich, has been elected an honorary member of the Royal Academy of Medicine of Barcelona for his researches on typhus fever recently made in Spain.

CORRECTIONS

The Typhoid Carrier State Treated with Sulfaguandine—In the clinical note by Major Robert J Hoagland in THE JOURNAL, Dec 12, 1942, page 1211, the dose of sulfaguandine used by Levi and Willen should have been written as 0.05 Gm per kilogram of body weight instead of 0.5 Gm.

Protective Ointment for Welders—In a Query and Minor Note entitled "Erythema from Welding" published in THE JOURNAL, January 9, page 162, an ointment for the protection of welders was suggested which would consist of zinc oxide ointment to which is added 10 per cent tannic acid or 5 per cent methyl salicylate. This should be menthyl salicylate, as should a similar reference below it.

Government Services

Urge Speedy Naturalization of Alien Physicians

Because of the acute shortage of civilian physicians throughout the United States, the Immigration and Naturalization Service has been directed to expedite the naturalization of alien physicians, according to a release from the Department of Justice January 16. Immigration Commissioner Earl G Harrison has issued instructions to expedite the filing of petitions for naturalization and to hold hearings in advance of their regular order on the calendar in the cases of practicing alien physicians or aliens who would be qualified to practice if they were citizens. In issuing the instructions, Commissioner Harrison pointed out that many states, either by statute or by the administrative ruling of licensing boards, require applicants to establish American citizenship before they are admitted to the state licensing examinations for the medical profession. Other states, he said, issue temporary licenses which are subject to cancellation unless citizenship is obtained within a specified period of time. The order expediting naturalization of physicians supplements instructions issued the service in January 1942 to expedite applications for citizenship submitted by aliens in the armed forces or engaged in national defense work. In the case of physicians they are not required under the new instructions to obtain a letter from a national defense agency testifying to the nature of their employment in order to secure national defense preference in naturalization. Attorney General Francis Biddle emphasized that the new procedure in no way affects the statutory requirements for naturalization but simply expedites the handling of applications.

Neurosyphilis and Delinquency

The high incidence of syphilis, particularly neurosyphilis, in criminals in Rio de Janeiro was emphasized some time ago by Dr. Cerqueira Luz, who found that the percentage of positive Wassermann tests in the blood of criminals in a large penitentiary (Casa de Detenção) was much higher than that of patients in the hospitals of the city, even those with a special clinic for neurosyphilis. In a recent paper Dr. Heitor Carrilho reports a study of 600 inmates of a hospital for the criminal insane (Manicômio Judiciário). The study disclosed that 134 of them (22½ per cent) had a positive Wassermann reaction in the blood. There was no especial difference in the percentage of positivity of the test in the blood among criminals according to the different types of delinquency: 197 per cent in crimes against persons, 24 per cent in crimes against property and 24 per cent in misdemeanors. The Wassermann test of the cerebrospinal fluid has been carried out on 500 inmates of the Manicômio Judiciário, 37 of them (7.4 per cent) having been positive. In this instance the percentage of positives is significantly different in the various classes of delinquency: 35 per cent in crimes against persons, 11.4 per cent in crimes against property and 8.6 per cent in misdemeanors. But these 37 cases do not represent all the instances of abnormality of the central nervous system among these persons. When all the various tests performed with the cerebrospinal fluid of the 500 inmates, i. e. the Wassermann reaction, the globulin reactions, the colloidal reactions and the cell count, are taken together, there are 277 cases in which one or more of these tests have been positive, showing that 55.2 per cent of the patients had inflammatory changes of the central nervous system, which strongly suggests neurosyphilis. In several cases of relapsing delinquency the repetition of the examination clearly demonstrated the presence of syphilis. Dr. Carrilho points out that the problem of relapsing delinquency finds in numerous cases an explanation which is well within the province of neuro-psychiatry.

The Health of Children of Persons Afflicted with Leprosy

In a recent paper Dr. Octavio Gonzaga and others of the Division of Leprosy of the São Paulo State Department of Health reported a survey of the health of children of leprosy patients inmates of the St. Teresinha Preventorium, founded in 1927. The institution at Carapicuíba, about 18 miles from the city of São Paulo, harbors 250 children from a few months to 13 years of age whose parents have leprosy and are now isolated in the state leprosariums. Among 73 deliveries at the maternities of these leprosariums during the year 1941 there were 9 stillbirths (12.3 per cent). The authors report a high morbidity and mortality rate for the children of the leprosy living in the crowded nurseries of the leprosariums (20 annual deaths per hundred infants received at the nurseries just after birth). The necropsy of 20 of these infants disclosed that 18 had died from acute infections of the respiratory tract, 1 from purulent meningitis and 1 from obstetric trauma. Many of the newborn have congenital debility, 85 per cent of them being under 7 pounds (3.2 Kg.) at birth and 25 per cent under 5 pounds (2.3 Gm.). The state of debility is much more com-

mon among the children from mothers affected with the lepromatous form of the disease than the ones from mothers with the pure nervous form. The leprosy of the fathers does not cause congenital malformations and degenerations among the children, who are normal in reference to stature, weight, morbidity and mortality rates, without any particular feature that may be related to a specific character of the father. No case of transplacental leprosy has been disclosed up to this date. In the careful observation of 300 children from leprosy parents, isolated just after birth up to the age of 13, as well as in 51 necropsies, the so called congenital leprosy has been so rare that the authors believe this expression may be considered meaningless. Among the 51 necropsies only 1 case presented a small papulous lesion of the face but the suspicion of leprosy was not confirmed by the careful examination of all the organs. In another case a large Ghon pulmonary focus and tuberculous lymphangitis made the search for the Hansen bacillus useless, owing to the concomitant tuberculous infection. The authors believe that the isolation of the children from the leprosy parents just after birth is sure protection against the later appearance of the disease.

When they are infected a short time after birth the infants present a high resistance to the disease. The authors think that the relatively mild course of the leprosy in children of tender age may be explained by the existence of an "extinct precocious leprosy" rather than by any natural individual resistance. In a majority of the cases the infant leprosy is of the mild tuberculoid type with a tendency to spontaneous cure. In the preschool and school ages on the contrary, the disease frequently takes a malignant character with a tendency to generalization. The use of the Mitsuda test on the children in the preventorium is very useful in disclosing the state of specific immunity to leprosy.

Personal

Dr. Olinto de Oliveira, professor emeritus of pediatrics of the Porto Alegre University and director of the National Department of the Child of Brazil, has been elected an honorary member of the Society of Pediatrics of New York. At the recent meeting of the South American Confederation of Pediatric Societies at Buenos Aires Prof. Aroaz Alfaro of that city proposed to bestow on Professor Olinto de Oliveira the special title of "Dean of the South American Pediatricians," which was approved unanimously.

Marriages

WENDELL PHILLIPS STAMPELI, Jr., Monahans, Texas, to Miss Carol Jean Wollins of Charleston, S. C. in Chicago, October 7.

DAVID SAMUEL GARNER, Romolc, Va., to Miss Willy Mae Webb of Delray Beach, Fla., December 2.

IRVIN THOMAS BLANCHARD, Woodland, N. C. to Miss Lois Jean Bateman of Tarboro, November 17.

BEATY LEE BASS, Lenoir, N. C., to Miss Patsy Smith of Winston-Salem, in November.

IRVIN B. TRAPP to Miss Anne McGovern, both of Philadelphia, Miss., November 21.

CHARLES SWIFT JONES, New York, to Miss Frances Bird of Valdosta, Ga., December 18.

WALSH McDERMOTT to Miss Marion Ann MacPhail, both of New York, November 11.

WALTER ELISHA HOOK to Miss Jerne Patricia Diehl, both of Chicago, December 26.

JACOB D. MATIS to Miss Rosalie B. Metzger, both of Brooklyn, October 11.

Deaths

Warren La Verne Babcock * Detroit, College of Physicians and Surgeons Baltimore, 1893 formerly associate clinical professor of neurology and psychiatry at the Detroit College of Medicine and Surgery, secretary of the American Hospital Association from 1908 to 1910 and in 1911 president, president of the Michigan Hospital Association, 1919-1920 and 1934-1935, president of the Wayne County Medical Society, 1917-1918 was commissioned a first lieutenant and later a major and a lieutenant colonel in the medical corps of the U S Army during World War I served as commanding officer of American Red Cross Hospital number 3 in Paris and later as commanding officer of Base Hospital number 6 in Bordeaux honorably discharged as a colonel in February 1919 was made an officer of the Legion of Honor of France in 1919 assistant physician at the Binghamton (N Y) State Hospital 1894-1895 and the St Lawrence State Hospital, Ogdensburg, from 1895 to 1902 chief surgeon of the New York State Soldiers' and Sailors' Home, Bath, N Y from 1902 to 1904, director of the Grace Hospital from 1904 to 1937 and treasurer and trustee since then treasurer and trustee of the Michigan Hospital Service, on the editorial board of *Hospitals* and formerly on the editorial board of *Modern Hospital*, aged 69, died, December 27, at his winter home in St Petersburg Fla, of coronary thrombosis

Thomas Wood Hastings, Kinderhook, N Y, Johns Hopkins University School of Medicine Baltimore, 1898 instructor of clinical pathology at the Cornell University Medical College, New York, from 1901 to 1906 and professor from 1906 to 1918, substitute clinical pathologist, Presbyterian Hospital, New York, from 1902 to 1904, assistant visiting physician Cornell Medical College Dispensary from 1901 to 1907, assistant visiting physician at the Bellevue Hospital, New York from 1908 to 1917 and acting visiting physician from 1917 to 1921 member of the consulting staff of the St Bartholomew's Clinic and Hospital, New York, 1920-1921 fellow of the American Association for the Advancement of Science, served in the Boer War in Africa, the Boxer Rebellion in China and during World War I, lieutenant in the medical reserve corps of the U S Army from 1910 to 1917, became a major in 1917 and retired with that rank in 1928, aged 69 died December 5

Elliott Gray Brackett * Boston Harvard Medical School, Boston, 1886 member of the American Academy of Orthopaedic Surgeons, fellow of the American College of Surgeons at one time assistant in orthopedics at his alma mater served as a colonel and as a director of orthopedic surgery in the U S Army during World War I one of the founders of the Industrial School for Crippled and Deformed Children a trustee and the first president of the Boston School for Occupational Therapy, served as chief of the orthopedic service at the Massachusetts General Hospital and as assistant surgeon on the staff of the Children's Hospital, editor of the *Journal of Bone and Joint Surgery*, aged 82 died December 29

George Riley Anderson * Brattleboro, Vt University of Vermont College of Medicine Burlington, 1898 fellow of the American College of Surgeons member of the New England Surgical Society, past president of the Vermont State Medical Society and of the Windham County Medical Society, veteran of the Spanish-American War served as chief surgeon on the staff of the Brattleboro Memorial Hospital consulting surgeon Brattleboro Retreat, the Rockingham General Hospital, Bellows Falls and the Springfield (Vt) Hospital surgeon to the Boston and Maine Railroad aged 67 died December 19 in Winter Haven Fla, of cerebral hemorrhage arteriosclerosis and diabetes mellitus

Henry Clay Lindersmith, Sherwood Ohio Barnes Medical College St Louis, 1894 member of the Ohio State Medical Association formerly served as health officer of Defiance County past president of the board of education of Sherwood and its first fire chief serving for many years, at one time member of the board of U S Pension Examining Surgeons and local surgeon for the Baltimore and Ohio Railroad aged 75 died, November 22, in the Mount Carmel Mercy Hospital Detroit of chronic myocarditis hemorrhages and gastric ulcers of long duration

Nagib Tannous Abdou, Utica N Y M B School of Medicine and Surgery of Montreal Faculty of Medicine of the University of Laval at Montreal in 1899 and M D in 1900 captain in the medical reserve corps of the U S Army not on active duty aged 67, died November 9, of coronary thrombosis

Arne O Arneson * McVille N D George Washington University School of Medicine Washington D C 1911 served as vice president of the North Dakota State Medical Association president of the Community Hospital aged 63 died, December 11

Bertha May Louise Lypps Bachelder, Pontiac Mich University of Michigan Department of Medicine and Surgery Ann Arbor, 1903 aged 65, died December 14 of carcinoma

Solomon Beck, New York Columbia University College of Physicians and Surgeons New York, 1910 formerly a pharmacist aged 76, died December 26

Theodore Beck, Pleasant Hill, Ohio Columbus Medical College 1892, aged 79, died, December 15

Gordian Edward Benes, St Louis National University of Arts and Sciences Medical Department St Louis 1913, aged 57 died December 9 of brain tumor

Charles Albert Briggs * Assonet Mass Long Island College Hospital, Brooklyn, 1889 had been school physician in Free-town and Berkley for many years aged 78 died, December 14 of cerebral hemorrhage

Thomas Preston Cochran, Pittsburgh Jefferson Medical College of Philadelphia, 1893 member of the Medical Society of the State of Pennsylvania for many years president of the staff of St Joseph's Hospital and Dispensary formerly president of the Lyman Building and Loan Association and a director of the Hill Top Bank aged 76 died December 5

John Elwood Cullum, Tulsa Okla International Medical Missionary Institute, Chicago 1900, Gate City Medical College Texarkana Ark, 1906 member of the Oklahoma State Medical Association, aged 83, died, December 6 of pneumonia and senility

Arthur Ward Detrick * New Carlisle, Ohio Starling-Ohio Medical College Columbus 1908 for many years had been a member of the advisory board of the Clark County Health Board aged 63, died December 3 of cerebral hemorrhage

Henry Trawick Donovan, Huntsville Ala Louisiana State University Medical Center, New Orleans 1934, formerly health officer of Shelby and Coffee counties aged 35, died December 7 in the Benevolent Society Hospital Decatur of injuries received in an automobile accident

Leverette Saltanstill Early * Petersburg Va University College of Medicine Richmond 1898 served in the medical corps of the U S Army during World War I local surgeon for the Norfolk and Western and Seaboard Air Line Railways member of the chamber of commerce aged 68 on the staff of the Petersburg Hospital where he died December 22 of multiple myeloma

Joseph Benjamin Edwards Swanser S C University of Maryland School of Medicine Baltimore 1911 member of the South Carolina Medical Association served as medical examiner for the Selective Service System during World War I served as a captain in the medical corps of the U S Army, won the Purple Heart and distinguished service citations chairman of the board of trustees of the Swanser public schools for many years aged 55 died December 14, in the Veterans Administration Facility Columbia of heart disease

George R Ernst * Wauwatosa Wis Rush Medical College Chicago 1901 L R C P London and M R C S England, 1904 associate clinical professor of medicine at the Marquette University School of Medicine Milwaukee formerly superintendent of the tuberculosis division of the health department of Milwaukee at one time superintendent of the Lincoln Memorial Sanatorium aged 73 died, December 3, of acute coronary thrombosis

George W Fiske, Rutland Vt University of the South Medical Department Sewanee Tenn, 1901 aged 81 died, December 6

John Edward Knight Flannagan * Richmond, Va University of Virginia Department of Medicine, Charlottesville 1925 formerly superintendent and medical director of the Roanoke City Tubercular Sanatorium Roanoke aged 43, died, December 2 in Wytheville of heart disease

Louis Fuldner Tryon N C Rush Medical College, Chicago 1895 aged 69 died, December 11

Thomas Monroe Garner, Somerset Ky University of Louisville Medical Department 1912 member of the Kentucky State Medical Association past president of the Pulaski County Medical Society aged 59 died December 6 of organic valvular disease of the heart

George John Geisler * South Bend, Ind., University and Bellevue Hospital Medical College, New York, 1915, served in France in the medical corps of the U S Army during World War I, major in the medical reserve corps, not in active duty, past president of St Joseph County Medical Society, on the staffs of the Epworth and St Joseph hospitals and the Children's Dispensary, aged 55, died, December 14, of coronary thrombosis and transverse myelitis.

Clarke Houston Gillespy * Birmingham, Ala., Tulane University of Louisiana School of Medicine, New Orleans, 1935, secretary treasurer of the Jefferson County Medical Society, member of the Southeastern Surgical Congress on the staffs of St Vincent's, Hillman and Children's hospitals, aged 37, died, December 14, of metastatic adenocarcinoma.

William N Goone * Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912, served as a captain in the medical corps of the U S Army during World War I, aged 56, on the courtesy staff of the Lutheran Deaconess Hospital where he died, December 27, of coronary occlusion.

Ivan Bowman Hards, Denver, Grand Rapids (Mich.) Medical College, 1902, member of the New Mexico Medical Society, aged 64, died, December 14, of cardiovascular renal disease.

William A Hoelscher, St Louis, St Louis College of Physicians and Surgeons, 1893, also a pharmacist, was vice president of the Cass Bank and Trust Company, where he had been a director for many years, aged 77, died, December 13, in Jacksonville, Fla.

George Michael Holley, Harrisburg, Pa., Temple University School of Medicine, Philadelphia 1930, aged 36, died, December 9, in the Good Samaritan Hospital, Pottsville, of amebic dysentery, hepatic abscess and diabetes mellitus.

Joseph Henry Kenealy, Chicago, Harvard Medical School, Boston, 1900, aged 64, died suddenly, December 2.

Elmer O Laughlin * Paris, Ill., Medical College of Ohio, Cincinnati, 1893, past president of the Aesculapian Society of the Wabash Valley, for many years surgeon for the Pennsylvania Railroad, a member of the library board and the city council, author of books and poetry, aged 75, died, December 14, of cerebral hemorrhage.

Herbert Edward Markwort, St Louis, St Louis College of Physicians and Surgeons, 1903, on the staffs of the Deaconess and St Mary's hospitals, aged 65, died, December 11, of heart disease.

Joseph Chandler Marshall, Atlantic City, N J, University of Pennsylvania Department of Medicine, Philadelphia, 1899, formerly on the staff of the Atlantic City Hospital, aged 69, died, December 20, of cerebral hemorrhage.

Henry Hamilton Mayne * Lockport, N Y, University of Buffalo School of Medicine, 1892, pension examiner for the United States government from 1905 to 1912, served as a captain in the medical corps of the U S Army during World War I, coroner of Niagara County from 1895 to 1897 and again from 1900 to 1902, medical officer of the public schools of Lockport, aged 78, for many years on the staff of Lockport City Hospital, where he died, December 17, of a cerebral hemorrhage.

Cicero M McCracken, Asheville, N C (licensed in North Carolina in 1896), member of the Medical Society of the State of North Carolina, was a member of the school board of Fairview, served on the county board of health, aged 74, died, December 8, of cardiorenal disease, hypertension and cerebral hemorrhage.

Thomas McLeod, Webster, Fla., Atlanta (Ga.) Medical College, 1892, aged 78, died, December 11.

Henry P Metcalf, Rushville, Ind. (licensed in Indiana in 1897), member of the Indiana State Medical Association, aged 86, died, December 15, of pulmonary embolus.

Robert Lewis Mitchell * Baltimore, University of Maryland School of Medicine, Baltimore, 1905, aged 61, on the staffs of the University Hospital and the Maryland General Hospital, where he died, December 13, of coronary thrombosis.

James Gordon Murfin, Portsmouth, Ohio, University of Pennsylvania Department of Medicine, Philadelphia 1902, served as a captain in the medical corps of the U S Army during World War I, served on the staff of the Schirman Hospital, aged 64, died, December 3, of edema of the lungs.

Prince Wellington Mynns, Brockton, Mass., University of West Tennessee College of Medicine and Surgery, Memphis, 1916, aged 60, was found dead, December 4.

Elizabeth Naomi Newcomb, Carleton, Mich., University of Michigan Homeopathic Medical School, Ann Arbor, 1916, formerly on the staff of the Woman's Hospital, Detroit, aged 57, died, December 7, in Detroit.

Arthur Thomas Piercy, Los Angeles, State University of Iowa College of Medicine, Iowa City, 1886, aged 85, died, December 3.

George Harris Richardson, Washington, D C, Howard University College of Medicine, Washington, 1890, formerly a lawyer, aged 88, died, December 2.

Howard Thomas Robinson * Cumberland, Maryland, University of Maryland School of Medicine, Baltimore, 1904, member of the American Academy of Ophthalmology and Otolaryngology on the courtesy staff of the Allegany Hospital of the Sisters of Charity on the staff of the Memorial Hospital, aged 62, died suddenly, December 3, of coronary occlusion.

Herbert Ulysses Seabrook, Charleston, S C, University of West Tennessee College of Medicine and Surgery, Memphis, 1914, aged 56, died, November 17.

Albert Stein * Thompsonville, Conn., University of Maryland School of Medicine, Baltimore, 1917, served during World War I, on the visiting staff of the Wesson Memorial Hospital, Springfield, Mass., aged 48, died, December 5, in the George F Baker Clinic of the New England Deaconess Hospital, Boston, of uremia, acute hemorrhagic nephritis and pulmonary edema.

George A Van Fradenburg, Montross, Colo., University of Denver Medical Department, 1898, aged 71, died, October 31, of carcinoma.

Richard Powers Wilkinson * Philadelphia, Medical-Chirurgical College of Philadelphia, 1899, formerly treasurer of the Philadelphia County Medical Society, aged 70, died, December 2.

William Douglas Wirt, Washington, D C, Columbian University Medical Department, Washington, 1887, aged 80, died, December 13.

Leo Zon, Baltimore, University of Minnesota Medical School, Minneapolis 1931, specialist certified by the American Board of Pathology, Inc., diplomate of the National Board of Medical Examiners, passed assistant surgeon, U S Public Health Service reserve, aged 36, for many years research pathologist at the United States Marine Hospital where he died, December 5, of meningococcal septicaemia and cerebrospinal meningitis.

DIED WHILE IN MILITARY SERVICE

Maurice Marshall Berek * New York, Cornell University Medical College, New York 1928, diplomate of the National Board of Medical Examiners, specialist certified by the American Board of Surgery, fellow of the American College of Surgeons, on the staffs of the Mount Sinai and Gouverneur hospitals, captain in the medical corps, Army of the United States, entered active duty at the Army Medical Center, Washington, D C, Nov 24, 1942, aged 38, died, January 4, in the Central Dispensary and Emergency Hospital, Washington, of asphyxiation, carbon monoxide, universal burns of the body and extremities, toxemia and shock, accidentally incurred when he probably fell asleep with a lighted cigaret in his hand and set his apartment on fire.

Lemuel Edward Day * Chicago, Rush Medical College, Chicago, 1925, fellow of the American College of Surgeons, member of the attending staff, chairman 1940-1941, section of obstetrics and gynecology at the Ravenswood Hospital, where he was president of the medical staff 1933-1934, served as second lieutenant in the field artillery during World War I, major in the medical corps in the Army of the United States, began active duty June 14, 1942, in command of the Second Field Hospital, New Guinea, where he died, December 22, of heart disease, aged 46.

Jacob Walter, Chicago, University of Illinois College of Medicine, Chicago, 1939, a first lieutenant in the medical corps of the Army of the United States, was called to active service Feb 5, 1941, stationed at the Milwaukee District United States Army Recruiting and Induction Service, aged 27, died, October 14, in the Veterans Administration Facility, Wood, Milwaukee, of lobular pneumonia.

Bureau of Investigation

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are brief abstracts of some fraud orders not dealt with previously.

International Laboratories—This is an outgrowth of or a new name for a Baltimore outfit that did an obesity cure mail order business under the name The Bradford Laboratories. The fraud order that banned the Bradford concern from the mails was dealt with in a lengthy article in this department of THE JOURNAL Jan 4 1941 pages 68-69. It was there shown that the Bradford outfit under one name or another had been in business over a period of more than forty years and at one time had claimed that its treatment was composed of a combination of roots and herbs no chemical preparations. Whereas it was represented still to be the original nostrum which chemical examination had shown to contain among other ingredients such minerals as baking soda and some bismuth salt perhaps a subnitrate. The Post Office fraud order that closed the mails to this scheme was issued Dec 1 1939. Like many other swindles it did not actually go out of business but simply changed names and continued to operate as before but under a new trade style International Laboratories Box 983 Baltimore which had been contrived by E. L. Kincaid the owner of the Bradford Laboratories. The actual address was 38 Hopkins Place Baltimore the same location from which the original enterprise had been conducted but the new name and address were calculated to throw the Post Office off the scent. That agency however detected Kincaid's effort to dodge the original fraud order and on Sept 29 1941 issued a new one debarring from the mails the name International Laboratories.

J. W. Dorman—This person first came to the notice of the Bureau of Investigation when on Oct 15 1934, trading as Dorman Chemical Company Concord N. C. he was fined \$100 and placed on probation for eighteen months after pleading guilty to violating the Pure Food and Drugs Act by shipping his J. W. D. Blood Purifier and undesignated pills and capsules in interstate commerce under the fraudulent label representations that the complete treatment was a blood purifier and general reconstructive tonic as well as a cure for pellagra kidney and heart disorders ulcerated stomach high blood pressure gallstone trouble skin diseases and some other conditions. This case designated by the government as Notice of Judgment 24515 issued in March 1936 was abstracted in THE JOURNAL Sept 25 1937. Dorman using not only his name but also the title The Medicine Man also sold his treatment by mail playing it up chiefly as a treatment for pellagra. In his circulars he claimed that he had once suffered from this disease in its worst form and that a hospital which treated him for it discharged him as an incurable patient. Thereupon if one could believe him he sought to relieve himself by experimenting with different herbs. He discovered a combination by which he was completely relieved. Since that time he has been making and selling this medicine to relieve other sufferers. Thousands have been completely relieved and there is no case recorded that we know which has failed to be relieved when the medicine has been taken according to directions. Testimonials the usual stock in trade of the patent medicine exploiter also were played up but when asked to produce the alleged originals of these he was unable to do so. Analysis by government chemists revealed that one part of the treatment J. W. D. consisted essentially of tincture of digitalis. Fowler's solution of arsenic salicylic acid coloring matter and water. The accompanying blue tablets contained copaliba cubebs methylene blue santal and kava kava and the white tablets were a mixture of aloes podophyllum colocynth scammony gamboge and about 0.8 grain per tablet of calomel the ointment contained sulfur petrolatum hydrous wool fat a hot principle a phenolic principle and a salicylate. As evidence of the scientific character of this treatment it is interesting to note that the Post Office investigation divulged that Dorman could neither read nor write and that the clerical details of his business had to be performed by his wife. When cited by the Post Office to appear at a hearing held on Jan 13 1937 and show cause why a fraud order should not be issued against his enterprise Dorman sent his attorney instead. Since the latter was unable to controvert the evidence presented by the expert medical witness for the government to the effect that Dorman's nostrums were wholly without value for pellagra his business was debarred from the mails by a fraud order issued Jan 25 1937 against the names J. W. Dorman.

The Medicine Man and Dorman Chemical Company. Some time thereafter according to a later Post Office investigation Dorman moved from Concord to Pineville N. C. where he continued to operate his scheme despite the original fraud order. In response to one inquiry he claimed that his present pellagra treatment was the same as the one he formerly had sold from Concord. When asked whether it would cure pellagra he sent the treatment through the mails for that purpose designating it as J. W. D. (An Alternative) Dorman's Diuretic Tablets and J. W. D. Laxative Tablets and a fine \$350 for the combination. A government chemist who analyzed the nostrums reported that the first named was a reddish pink liquid containing total medicinal matter amounting to 0.04 grain per teaspoon and containing in each teaspoon 0.009 grain of arsenic trioxide 0.02 grain of salicylic acid

and a trace of wintergreen. The diuretic tablets were found to contain copaliba cubebs methylene blue antial oil and kava kava and the laxative tablets consisted of rhubarb colocynth compound and about 8/10 of a grain of calomel. When Dorman was notified by the Post Office to show cause why a second fraud order should not be issued against him he neither put in an appearance nor sent anyone to represent him his sole defense being a written answer to the charge. An expert medical witness familiar with pellagra testified for the government that this is a vitamin deficiency disease manifested by many symptoms and that the present recognized treatment for it is the administration of nicotinic acid in large dose together with an abundance of other vitamins such as thiamine (B₁) and riboflavin (B₂) as well as proper diet. Since it was shown that Dorman's group of nostrums would not cure or alleviate pellagra and that in fact the use of a laxative such as his treatment included might set up an intractable diarrhea endangering the very life of the sufferer it was declared to be a scheme for obtaining money through the mails by means of false and fraudulent pretenses representations and promises and an evasion of the fraud order of Jan 25 1937. A supplemental fraud order accordingly was issued on Oct 28 1942 against J. W. Dorman of Pineville N. C.

Montana October Report

The Montana State Board of Medical Examiners reports the written examination for medical licensure held at Helena Oct 6-7 1942. The examination covered 10 subjects and included 50 questions. An average of 75 per cent was required to pass. Eight candidates were examined, 7 of whom passed and 1 failed. Six physicians were licensed to practice medicine by reciprocity and 3 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad	Number Passed
University of Minnesota Medical School		(1935)	1
Creghton University School of Medicine		(1942)	2
Ohio State University College of Medicine		(1942)	1
Medical Department of Grant University		(1942)	1
Marquette University School of Medicine		(1942)	1
Universite de Lausanne Faculte de Medecine		(1936)	1
School	FAILED	Year Grad	Number Failed
Universitat Zurich Medizinische Fakultat		(1940)	1
School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
College of Medical Evangelists		(1930)	Calif. and
Rush Medical College		(1937)	Missouri
University of Minnesota Medical School		(1926)	Minnesota

University of Manitoba Faculty of Medicine	(1930)	N Dakota
University of Toronto Faculty of Medicine	(1895)	Michigan
LICENSED BY ENDORSEMENT

Maryland June Report

The Board of Medical Examiners of Maryland (Homeopathic) reports the written examination for medical licensure held at Baltimore June 16-17, 1942. The examination covered 9 subjects and included 70 questions. An average of 75 per cent was required to pass. Four candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year	Number
		Grad	Passed
Hahnemann Medical College and Hospital of Philadelphia	(1941-3)	(1942)	4

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Right to Require Alleged Incompetent in Guardianship Proceedings to Submit to Mental Examination— Redfield applied to the superior court King County Washington, for the appointment of a guardian of the person and estate of his sister, alleging that she was incompetent mentally and physically to care for herself or her estate. Subsequently the trial court ordered three psychiatrists, named by Redfield, to examine the alleged incompetent to enable them to testify later as to her physical and mental condition at the hearing on the petition for the appointment of a guardian. The state, then, on the relation of the alleged incompetent, brought certiorari to the Supreme Court of Washington to review the propriety of the trial court's order.

While Redfield cited no court decision which specifically held that in a guardianship proceeding the trial court may, before a hearing, direct that the alleged incompetent submit to an examination by physicians named by the court to conduct such an examination, he contended that such power is included in the general inherent authority of the court to conduct guardianship proceedings and to take such steps as may be deemed advisable in order that a full and complete hearing may be had. Apparently as authority for an order such as was under question he relied on *Lane v. Spolane Falls & Northern R. Co.* 21 Wash. 119, 57 P. 367, in which the Supreme Court of Washington held that the trial court possessed inherent power to require a plaintiff in a tort action for personal injuries to submit to a pretrial examination by medical experts appointed by the court for the purpose of ascertaining the nature, character and extent of the plaintiff's injuries. The Supreme Court, however distinguished that case from the facts here involved. Obviously said the court, when a person voluntarily brings an action for the recovery of damages on account of personal injuries alleged to have been suffered the court should have the power to direct that prior to the trial the plaintiff submit to a physical examination. There is no statute in this state authorizing such action in an adversary proceeding for the appointment of a guardian of an alleged incompetent nor would such a right seem to be vested in the court at common law. The right of a court to order a party to submit to a physical examination was recognized at common law in certain classes of actions such as proceedings for divorce in cases in which it was desired to make proof of cohabitation and in criminal prosecutions for mayhem. The right of the court in Washington is somewhat broader than at common law because of a Washington statute (Rem. Rev. Stat. sec. 6930) which provides that when it is charged under oath that a person by reason of insanity is unsafe to be at large the court can require the alleged incompetent to submit to examination by two reputable physicians. But this procedure applies only under and is limited to the circumstances mentioned

The authority assumed by the trial court, continued the Supreme Court, in ordering the alleged incompetent to submit to an examination to be conducted by physicians designated by the person seeking the appointment of a guardian trenches to a great extent on the liberty of the individual. One in the alleged incompetent's situation is not a voluntary participant in such a proceeding as this. The proceeding is adverse to her. It may be assumed that, in the great majority of cases no petition alleging incompetency would be filed unless at least some ground existed for such a charge. Assuming then, that the alleged incompetent is physically or mentally ill, the charge of incompetency itself would naturally have a bad effect on the person and tend to aggravate any unfortunate existing condition. If, in addition to the charge the alleged incompetent must submit to the ordeal necessarily involved in a lengthy physical and mental examination by three physicians known to have been chosen by the adverse party, the effect would probably be very bad and might be serious. There would be no way of terminating the examination until the examining physicians chose to end it and its undue extension might well be most unfair and harmful to the subject. Neither would there be any control of the questions that the examiners might ask and, even though the subject might be represented and advised by counsel, the mere persistent asking of improper questions might well irritate the person examined and produce unfortunate results.

A petition for the appointment of a guardian on the ground of mental incompetence continued the court may be filed against any person at any time. If the procedure embodied in the order now before this court for review may be established, it might be used improperly and for some ulterior purpose entirely disconnected from any question of guardianship. In the absence of any controlling authority, such as the presence of the judge much harm might result. Certainly no such step should be taken unless the judicial authority to make the order clearly appears and some very real emergency should be shown to exist. The order of appearing in court or even knowing that such a proceeding has been filed, is considerable but those consequences cannot be avoided. In open court the alleged incompetent has the benefit of judicial protection. If, in the course of the hearing before the court on the application for appointment of a guardian, the court feels that the evidence produced is inadequate or for any reason unsatisfactory and for its own information desires further testimony, a different situation might arise concerning which we here express no opinion. The effect of holding the procedure followed in entering the order under review proper would seem to encourage the filing of a petition for the appointment of a guardian since a petitioner could use physicians of his own selection by way of an exploring expedition to see what they could discover in examining an alleged incompetent. In this case the order provided that the three physicians named should make only one examination of the alleged incompetent and that the time should suit her convenience but even with that restriction the accomplishment of the order would require that the alleged incompetent undergo a very trying ordeal, which might have to her injurious consequences.

The order in question the court accordingly held, was entered without warrant of law and infringed the alleged incompetent's lawful rights to personal peace and security. The order requiring the alleged incompetent to submit to examination by physicians designated by her brother was reversed.—*State ex rel. Nelson v. Superior Court of King County* 131 P. (2d) 144 (Wash. 1942)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Id. IV. Vasodilators and Coronary Circulation. Experimental Observations. A. Leslie and M. G. Mulinos. New York—p. 679.

Weltmann Serocoagulation Band—The interest of Delaney and Keyes in the application of the Weltmann serocoagulation test in coronary artery occlusion was aroused by the parallelism between this test and the sedimentation rate and leukocyte count in other conditions characterized by tissue necrosis. The coagulation band of the Weltmann serocoagulation test was considerably shortened in 24 cases of coronary artery occlusion. The coagulation band became progressively shortened during the early acute stages of infarction beginning on the second or the third day, and reached its minimum by the fifth to the seventh day. This "shift to the left" afforded some index of the extent of myocardial necrosis. An abrupt, extreme or persistent left shift would indicate either a large infarction or slow healing and therefore a more serious prognosis. Conversely a coagulation band which is only moderately shortened or promptly returns to normal was associated with satisfactory healing and a good prognosis. As repair proceeds by fibrosis the coagulation band lengthens again to normal. Large areas of fibrosis, old or recent, result in a shift to the right, beyond normal. The Weltmann reaction may serve as a manifestation of the actual pathologic course of the disease. In coronary artery insufficiency, which produces myocardial ischemia without actual infarction, the coagulation band is unchanged. Therefore the Weltmann test is useful in differentiating between the two conditions. The conditions (pregnancy, the ingestion of food and destructive changes in the body) that cause variations in the sedimentation rate are not observed to do so in the Weltmann test, which more closely reflects the true nature of the pathologic change and the clinical course of the patient. There was a close parallelism between the Weltmann coagulation band and the nonfilament count. The two complicating factors which must be considered in interpreting the coagulation band are the presence of old or new fibrotic processes of cardiac or extracardiac origin and myocardial insufficiency. The data obtained from a frequent charting of the Weltmann serocoagulation reaction are superior to those obtained with any other single procedure.

Diagnostic Value of Electrocardiogram—The electrocardiographic and the necropsy observations of 149 consecutive cases were compared by Katz and his co-workers. In cases of combined hypertrophy of the right and left ventricles the electrocardiogram usually reflected only the predominant ventricular

strain. Right ventricular preponderance was more often correctly diagnosed and less often overlooked than left ventricular preponderance. However, decided hypertrophy, especially if both ventricles are involved, may be present without electrocardiographic evidence of ventricular strain. Old healed infarction of the anterior wall may be indistinguishable from left ventricular hypertrophy without myocardial infarction. Conversely, left ventricular hypertrophy may give rise to an electrocardiographic pattern suggestive of recent infarction of the anterior wall. The electrocardiographic pattern of congenital heart disease was diagnostic. The patterns associated with recent myocardial infarction were significant although errors did occur, but errors were less likely when chest leads and serial curves were obtained. Old healed myocardial infarction, coronary sclerosis and myocardial fibrosis commonly failed to produce any characteristic electrocardiographic pattern. The electrocardiographic localization of myocardial infarction was correct in all but 1 case of old healed infarction. In the 2 cases of infarction of the lateral wall there were anterior wall patterns in the limb leads. Recent diffuse pericarditis was recognized in the electrocardiogram in the presence of associated masking conditions. The patterns of acute cor pulmonale were diagnostic, but extensive massive pulmonary embolism may occur without these patterns. Chronic cor pulmonale may produce a diagnostic pattern. The mitral P wave pattern is indicative of left auricular involvement, and in the present series it constituted electrocardiographic evidence of rheumatic heart disease.

Vitamin B Complex Deficiency in Sedentary Men—Egana and his collaborators show that a diet grossly deficient in the vitamin B complex causes subjects to become deficient (as determined by urinary excretion) within three or four weeks, that there is measurable physical deterioration in this time and that brewers yeast is a complete and adequate supplement to the deficient diet. The subjects used were 7 healthy physicians. The symptoms of physical deterioration were mild and vague, the most constant being easy fatigue, loss of ambition and loss of efficiency in daily work. Physical fitness for exhausting exercise and particularly recuperation between repeated periods of exhausting exercise were moderately deteriorated. The changes were reversed by adding brewers yeast to the diet. All other metabolic measurements showed slight or no abnormal changes. These measurements were oxygen consumption, carbon dioxide excretion, blood lactate, blood pyruvate, blood sugar, urine lactate and urine pyruvate. Cardiovascular changes were inconstant; there never was a tachycardia on exertion. On the contrary, abnormally slow heart rates in moderate exercise and in exhausting exercise were the rule. Blood pressure did not change. The electrocardiogram of only 1 subject showed significant changes.

"Shock Delaying" Action of Barbiturates—According to Beecher and his co workers the observation of Seeley, Essex and Mann that shock produced in dogs by exposure and manipulation of the intestine is slower to appear when barbiturate (sodium amytal) anesthesia than when ether anesthesia is used has been confirmed. There was no significant delay in the onset of shock produced by hemorrhage when barbiturate (sodium amytal) or ether anesthesia was used. This observation indicates that the barbiturates as compared with ether anesthesia are not useful in delaying all types of shock. The barbiturates appear to delay shock in comparison with ether only when the trauma is associated with loss of plasma from wound surfaces. The recommendation that barbiturates be administered to all wounded men if shock is anticipated involves two major assumptions, both of which, on the basis of the available information, are untenable. First, the recommendation that barbiturates be given all seriously wounded men assumes that the barbiturates will be of value in all types of shock which is not the case. The assumption that such administration of barbiturates will not be dangerous is contradicted by abundant evidence. Second direct application as a shock delaying or preventive requires the assumption that comparison of the barbiturate data with the ether data is the same as a comparison of barbiturate data with a condition of no anesthesia. No data are available to indicate that the onset of shock is slower under barbiturates than in the unanesthetized subjects. In experiments the administration of approximately 100 per cent oxygen did not significantly delay, in comparison with room air, shock due to bleeding under a barbiturate or ether anesthesia.

Gangrene Following Fractures—Child reports the fifteenth case of noninfective gangrene following fracture of the lower leg. In his patient who was 23, a careful analysis of the complication reveals two features of significance. 1 The nerve supply of the lower leg and foot, which was intact on admission, failed during the next two or three days. 2 The blood supply of the foot, which also was normal on admission showed early signs of embarrassment followed, however, by ultimate survival of the member. With these facts in mind it is possible to reconstruct the course of events that led to the complication. As a result of the severe crushing nature of the injury the anterior tibial artery probably was torn sufficiently to damage its intima, and a thrombus began to form at the site of the injury. During the next few days the thrombus became so large that it occluded the lumen of this vessel. Dependent on the progressive nature of this lesion were the clinical phenomena, namely the intact nerve and blood supply on admission their eventual

failure as the integrity of the blood supply became compromised and finally gangrene and complete loss of sensation. The ultimate viability of the foot may in all probability be ascribed to the rich collateral circulation about the ankle joint and between the distal branches of the anterior and posterior tibial arteries in the foot, but although this was abundant it was inadequate to supply in retrograde fashion the proximal portion of the anterior tibial arteries. To establish the validity of these assumptions the 14 cases of this complication appearing in the literature from 1850 to the present time are reviewed. Analysis reveals that the average age for the 15 was 26 years, and therefore degenerative diseases of the arterial wall as predisposing factors can be discounted. With two exceptions the fractures were extensive and involved both bones of the lower leg. The sites of fracture were about evenly distributed between the upper, middle and lower thirds of the lower leg, some were compound, some oblique, some transverse and many were comminuted. Apparently no particular site or type of fracture was especially predisposing. The gangrene in 9 involved the lower leg and foot, in 5 the foot alone and in 1 only the lateral muscles of the calf. The condition in all but 2 required that amputation be carried out. The site of the occlusive process in the other 13 was located, in 4 it was the popliteal, in 8 the anterior and posterior and in 1 the posterior tibial arteries. The complication in all probability does not appear to be related to the method of immobilization employed. Of the 2 patients on whom amputation was not done, the 1 who refused amputation was left with a useless leg and 1, the author's patient, is left with a foot which functions only partially even when supplemented by a brace. There were no deaths.

Carcinoma of Duodenum—A proved case of primary carcinoma of the infrapapillary portion of the duodenum is presented by Berger and Koppelman who discuss the roentgen, operative and necropsy observations from a clinical point of view. In the literature on all types of primary duodenal carcinoma 386 proved cases are reported to date, of which 199 per cent were suprapapillary, 65 per cent peripapillary and 15 per cent infrapapillary. Earlier diagnosis depends on the clinician's awareness that the diagnosis of duodenal carcinoma is possible though rare (from 0.03 to 0.003 per cent of all necropsies). Roentgen examination is especially helpful if the lesion is looked for consciously. While the results of radical surgery in duodenal carcinoma have been discouraging (52 per cent five year cures), with earlier diagnosis and with the present improved methods of preoperative and postoperative care the prospect for the future looks brighter, since a rational surgical technique is available for each type of case and since metastasis at the time of exploration is low.

Transitions in Physical Treatment of Poliomyelitis—

A comparison of observations in cases of poliomyelitis treated by early immobilization and by the Kenny method suggests Wright states, that early judicious use of fomentations and physiologic movements as pain and tenderness subside tend to absorb products of effusion, relieve muscular spasm and limit scar tissue which may ensnare normal neuromuscular units. Thus residual paralysis may be confined to the neuromuscular units which have been primarily and permanently injured by the virus. The rationale of making a transition from the early rigid rest and splinting to starting physical treatment immediately after diagnosis is confirmed. Wright believes that Miss Kenny's most important contribution to the treatment of infantile paralysis is in arousing the medical profession to use her method early in the acute stage of the disease and thus prevent much impaired circulation, fibrosis, loss of muscle sense and restriction of joint action so common when early treatment consisted of rigid rest and extensive splinting. Much of the residual damage to patients so treated was probably due to muscular spasm that was never relieved by immobilization.

Kenny Treatment for Infantile Paralysis—Knapp discusses muscle spasm, mental alienation and incoordination, the three basic ideas which differentiate the Kenny conception of the symptomatology of infantile paralysis. Paralysis is common to the two concepts. Muscle spasm is one of the basic symptoms—it is an involuntary and uncontrollable shortening of muscle fibers. This spasm is not to be confused with the spasticity of an upper motor neuron lesion which will relax under steady tension. Some of the possible local mechanisms responsible for the spasm are inflammatory or toxic changes and circulatory changes resulting in localized anoxia. However, the local condition may also be due to changes in the central nervous system. The so called irritative cord lesions may account for spasm. As denervated muscle is hypersensitive to acetylcholine, local spasm could be caused by a pathologic change in the cord. It is probable that fibrosis and contractures may be due to anoxia caused by spasm. It also seems reasonable that permanent pathologic changes may thus be produced by the spasm itself, even without extensive loss of motor cells. Consideration of these factors lends weight to the argument that muscle spasm should be treated and relieved as soon as the diagnosis has been made and that splinting, which favors spasm, should be avoided. Mental alienation is probably a physiologic block in conduction as contrasted with an anatomic block caused by destruction of anterior horn cells. Under this term may be included temporary paralysis produced by nonlethal damage to the nerve cells which recover spontaneously after the infection has subsided. Kabat has suggested the term "reversible paralysis" instead of "mental alienation." The conception of "mental alienation" is a valuable one if for no other reason than to suggest a possible effective treatment. Incoordination means that, because of disturbances in the normal motor patterns as a result of paralysis, alienation or spasm new motor patterns are developed which must become normal before normal action can occur. Evidence for the support of this idea is supplied by numerous patients who have been treated by the Kenny method months or years after unsuccessful treatment by conventional methods and who have been able to walk without support or have been able to use parts which previously were useless. The increase in useful function is due not to increase in power but to increase in coordination and decrease in limitation of motion from muscle shortening so that the efficiency of the muscle is greater.

*Sulfonamide Film for Use as Surgical Dressing Preliminary Report K L Pickrell Baltimore—p 304

Sulfonamide Film as Surgical Dressing—While studying various drying agents and plastic substances it occurred to Pickrell that a preformed sulfonamide film might serve a useful purpose in surgery. The film is made in the following manner: An emulsion is prepared containing 3 per cent of sulfadiazine or sulfanilamide, 25 per cent of methyl cellulose, 3 per cent of triethanolamine and 0.5 per cent of sorbitol with 50 per cent alcohol or acetone added to make 100 cc. The resulting emulsion is sprayed with a pressure gun or paint spray on a smooth horizontal glass surface. This is allowed to dry if acetone is used drying is extremely rapid but if 50 per cent alcohol is used several hours at 75°C are required before the film can be removed in a single sheet. The films are stable and can be sterilized by dry heat. Composition studies reveal that the film ordinarily contains 35 to 50 per cent of the sulfonamide compound. When a segment of the film is placed beneath the skin of a rabbit the sulfonamide can be detected in the blood within several hours. At the end of twenty-four hours disintegration of the film is almost complete. The author has used these sulfonamide films for 50 patients with burns in whom a surgical detergent was used to clean the burned surface and the surrounding skin if it was grossly contaminated. The area was then washed with saline solution, sulfadiazine or azochloramide solution. While the surface was still moist the sulfonamide film was placed to overlap the burned surface. A smooth, firm pressure dressing of gauze was then applied. This film remains in place for three to five days, at which time epithelialization will be taking place in second degree burns. Since the film is translucent, the injured area may be inspected without removing it. In third degree burns and in exudative lesions the film may be renewed as desired. The film has also been used to cover recent incisions, lacerations and abrasions to prepare granulating areas for grafting to cover the recipient and donor graft areas at the time of grafting to cover abraded and ulcerated areas and as a framework to hasten closure and regeneration of perforated eardrums. If low concentrations of the sulfonamides were used in the films infection was likely. Sulfadiazine films appeared to offer greater local protection against infection than did the sulfanilamide films. Pickrell feels that these preformed films may find a definite place in surgery for the hospitalized and ambulatory patient and in cases in which infection is imminent and surface drying is desired or when moisture, coincident with the use of ointments and its resulting maceration, is to be discouraged.

Sulfonamides and Surgery—In 100 consecutive surgical cases in which infection was established in 79 at operation and potential in 21 Warr and Campelli applied the sulfonamide compounds locally whenever possible and also systemically by the oral or the parenteral route. The results in traumatic wounds and in intestinal anastomosis were extremely gratifying. In large, extensive surface wounds, exemplified by the radical mastectomy, there was a striking increase in bleeding and serum formation. The use of these drugs in such wounds has been discontinued. Primary closure and healing of infected wounds with the use of the drugs was most gratifying. Sodium sulfathiazole may be administered in a 0.5 per cent solution in isotonic solution of sodium chloride by hypodermoclysis. A stronger solution cannot be used beneath the skin. No severe or permanent adverse reactions were encountered.

Treatment of Bacillary Dysentery—The general regimen that Poth and his collaborators carried out in treating patients with bacillary dysentery included the administration of adequate parenteral fluids and electrolytes to combat dehydration when this was indicated, no transfusions of whole blood or plasma for the dysentery and succinyl sulfathiazole by mouth in a daily dose that varied from 0.25 to 1 Gm per kilogram of body weight. The total daily dose was given in six equal portions. The length of treatment varied from two to seven teen days. There were no failures and no deaths. The ages of the patients ranged from 8 weeks to 83 years. The response of children and infants was prompt whether treatment was begun early or late in the disease. The response was equally good with small as well as with large doses. The temperature returned to normal in twenty-four hours or less in 9 of 10 instances. In the exception the time was thirty six hours. The response of 10 adults to therapy was also prompt regardless of the duration of the disease. Bacteriologic studies showed that *Shigella paradyenteriae* was especially susceptible to the antibacterial action of succinyl sulfathiazole. The dysentery organisms ordinarily disappeared from the stools within forty eight hours whereas significant lowering of the coliform bacteria required two to three days of additional therapy. The drug was equally effective in the acute and the more chronic forms of the disease. No untoward toxic manifestations ensued.

Bromsulphalein in Low Grade Chronic Illness—The hepatic function of 112 ambulant patients with low grade chronic illness probably secondary to chronic infection was determined by the Stiles and Kolb. The bromsulphalein test was used for the determination. MacDonald's normal criterion of complete elimination in twenty five minutes of a dose of bromsulphalein equal to 5 mg per kilogram of body weight was adopted. In all but 16 evidence of hepatic dysfunction was obtained. Of the remaining 96, more than 20 units of bromsulphalein was retained by 33. The mean retention of patients between 21 and 40 was less than the general average and that of patients more than 60 was greater, but the actual significance is uncertain. When the mean bromsulphalein retention of patients with mild general symptoms was compared with the mean retention of patients with moderately severe and severe symptoms, the differences were statistically significant, the respective values being 10.189 and 44.7 units. While the bromsulphalein retention by patients with high sedimentation rates tended to be high, there were some with high rates whose retention was low and some with low rates whose retention was considerable.

Fat Metabolism in Acne Vulgaris—Lippman and Zugerman state that a study of the fat tolerance, indicated by blood cholesterol changes following the ingestion of fat, of 20 patients with acne vulgaris failed to reveal any difference from that of patients without acne.

Ureteral Transplantation for Bladder Cancer—Jewett designed a special electrode for establishing an adequate and permanent ureterointestinal ostium and then a simple two stage method of implanting two intact ureters simultaneously into the sigmoid in cancer of the bladder. He has completed both stages of the ureterointestinal implantation in 15 instances. Thirteen of the patients had extensive vesical carcinoma and 2 did not have cancer, so they consequently did not have cystectomy but they fell in the same age group and were totally incapacitated by a deep seated infection of the bladder. Nine of the 15 patients are now living, the longest postoperative interval has been one and a half years. Of the 6 who died 3 did so during convalescence and 3 after discharge from the hospital. In one of the hospital deaths the cause was attributable to an error in technic

An early model of the electrode did not work satisfactorily and extensive sloughing followed. The second patient died of sudden cardiac failure and the third of a volvulus of the lower ileum which was not related to the ureterosigmoidostomy. Of the 3 who died after discharge, 1 died in nine months from metastasis, 1 in six months from local recurrence of the carcinoma in the pelvis, probably with metastasis, and 1 died two months after operation, three weeks before death this patient's postoperative condition was excellent and there was no obstruction of the urinary tract. The attending physician thought that death was due to ascending renal infection. Necropsy was not obtained. The condition of most of the 15 patients was considered hopeless and every form of therapy had been tried elsewhere before transplantation of the ureters was done. The author believes that the mortality among patients of better surgical risk could be reduced considerably.

Frog Pregnancy Test—Weisman and his colleagues have used the African clawed frog (*Xenopus laevis*, Daudin) in determining pregnancy in 267 women. In 154 the frog test was run parallel with the rabbit test and in 113 the tests were subsequently checked by physical observation and roentgenograms. The frog test was made with the urines of women who had missed not more than one menstrual period and who thought that pregnancy was possible. None could be diagnosed as pregnant or nonpregnant by physical examination. Of the 154 tested by both the rabbit and the clawed frog test, 148 were correctly diagnosed by both methods. The six discrepancies on further testing revealed the rabbit test to be in error in each instance. Of the 113 tested with the frog alone, 112 were diagnosed correctly and 1 incorrectly. The error was made on a woman who was seven days overdue in her menses, frog tests one week later showed a strong oviposition. The test has a number of advantages over other tests used for the diagnosis of pregnancy. It takes only six to twelve hours, it is 99.6 per cent accurate, it is simple to perform, the frogs are easy to maintain, the test is inexpensive as the animals can be used repeatedly, and the reading of the reaction is simply the gross observation of eggs in the water.

Local Anesthesia in Obstetrics—Some of the advantages of local anesthesia in obstetrics and gynecology that Greenhill mentions are that there are practically no pulmonary, local or general complications, the mortality is negligible, there are no ill effects to the liver, lungs, heart, circulatory apparatus and central nervous system, bleeding in the field of operation is decidedly reduced, there is no asphyxia of the child, haste in operating is unnecessary and wound infection is decreased. Local anesthesia, the author states, should be used more widely by obstetricians and gynecologists, as it definitely decreases the mortality and morbidity. The obstetric indications are, in part, dilation and curettage for incomplete missed and therapeutic abortion, hydatidiform mole, spontaneous delivery, episiotomy and repair, low forceps delivery, cesarean section and Porro operation. The gynecologic indications are dilation and curettage, plastic operations on the vagina, Manchester operation, Le Fort operation, vaginal hysterectomy, salpingectomy, oophorectomy and hysterectomy.

Fatigue Fracture of Tibia—Since 1931 Hartley has seen 14 patients complaining of pain in the calf or near the upper end of a tibia, and generally to the inner side. There is little to see or feel and roentgen study reveals changes which, in an early case, suggest an incomplete tibial fracture from $2\frac{1}{2}$ to 3 inches below the knee joint. A small knuckle of callus is usually visible at the inner or posterior aspect of this level. In 3 patients the condition was bilateral, which observation can lead only to the diagnosis of fatigue fracture in a person between 7 and 20 years of age. The most recent case has demonstrated the need for recognizing this condition during war, for in this instance an erroneous diagnosis led to severe fracture of the tibia and fibula in an active recruit, and consequently to prolonged immobilization. Now that adolescent groups are liable for war service, the incidence is likely to be greater, since fatigue fracture is more common in adolescence. Generally there is no history of injury or of violence. Nine of the author's 14 patients had no history of injury, 4 had a history of a recent fall or blow and 1 thought he had fallen. The only constant symptom is pain on standing, on walking or after walking. This may be either behind the knee, in the calf or over the inner aspect of the upper third of the tibia. There is no pain when the leg is at rest. So far no patient with bilateral involvement has complained of pain in both legs. Slight swelling on the inner aspect of the upper end of the shaft of the tibia was present in only 5 cases and tenderness in 3. Spontaneous cure results from nothing more than rest from weight bearing for several weeks. The condition may be due to faulty crystal structure of bone at this area of maximal strain and/or to abnormal strain at an already considerably weak site. It is essentially a fatigue dystrophy. Its roentgen appearance and healing are similar to march fracture of the metatarsals. It is not due to infection, bone tumor, Looser's umbauzonien, syphilis or tuberculosis.

Blast Effect in Warfare—Williams believes that it is important to determine which of the three components in the compound blast wave in air is the traumatic factor and how it affects the body. The effect of the negative air suction wave cannot be neglected. This wave has a great amplitude, as it starts at the peak of the positive pressure and descends slowly to below atmospheric pressure. Sudden decreases in air pressure, the negative phase of the blast wave, is certainly likely to be injurious to human lungs already damaged by the positive phase. The third blast component of mass movement of air or gas is capable of inflicting injury and is responsible for the shattering effects produced in the immediate vicinity of an explosion. In water, where mass movement is of a small degree even in close proximity to an explosion, these shattering effects are not observed. Contusional effects can be produced by the rush of gas from an explosion irrespective of any damage which the pure pressure wave may have caused. The lesions caused in water are due to a single high pressure wave, and there is no question of a wave descending the trachea or an after suction

wave. The effects on the body of explosions, both in air and in water, are primarily due to the externally applied pressure wave, but in air both the windage factor and the after suction waves play their part. Internal injury due to blast without external marks of violence is rare. Only 4 such cases were encountered among 1,500 casualties—in practically every instance a coexisting wound due to crushing, asphyxia and the like will be evident.

Depth Charges and Pathologic Changes—Should a depth charge, mine or torpedo explode in the vicinity of where a ship's company is in the water after the sinking of their ship there is grave danger of most of the men losing their lives. The clinical manifestations of patients who have suffered from water blast vary from slight spinal concussion accompanied by bloody diarrhea to laceration of the abdominal organs and lungs. The mortality from water blast is high and it is conceivable that many war casualties are due to this factor alone. With the object of finding out the real causation and mechanism of the thoracic and abdominal lesions and also to see if any form of simple protection could be devised, Cameron and his collaborators carried out a series of animal experiments. Microscopic examination has confirmed naked eye observation that the most important structural changes produced by a depth charge are in the respiratory system. There is a striking similarity in the nature of these effects, the main variation being in their intensity and distribution. The pulmonary changes are hemorrhage and emphysema with rupture of air spaces. Study of the pulmonary changes leads to an elucidation of the mechanism of depth charge effects. The most severe injury was seen in animals which were within a radius of 40 yards from the depth charge. Eleven of 13 animals within this radius were killed instantly, 10 showed extensive pulmonary hemorrhage and 5 moderate to severe interstitial emphysema. Hemorrhage may, however, develop in animals as far away as 100 yards. Severe pulmonary hemorrhage may occur without immediate death while animals may be killed at once and not show definite pulmonary lesions. Hemorrhage is present more frequently in the right than in the left lung, the upper lobes and margins of the lung are the most common sites involved. Bronchi may become filled with large blood clots, while small hemorrhages sometimes develop in the walls of the trachea and bronchi. Acute vesicular and interstitial emphysema are practically constant in animals within 40 yards of the depth charge. Emphysema affects the upper lobes of both lungs most often being least frequent in the lower lobes. Pneumo thorax and hemothorax are sometimes concomitant. Little damage is produced in the soft structures of the wall of the body and the bones. There is no special tendency for certain hollow viscera containing fluid, such as the gallbladder and urinary bladder, to be involved.

Nutritional Iron Deficiency Anemia—Davidson and his colleagues assessed the iron deficiency of 442 infants and preschool children from 2 to 4 years of age and of 389 children from 5 to 12 years of age attending two primary day schools in Edinburgh. A comparison of the hemoglobin levels of children 2 to 23 months of age in the present Edinburgh series with the figures for an Aberdeen series indicates that the incidence of severe anemia (less than 61 per cent of hemoglobin) in the 1935 Aberdeen series is three times as great as in the 1942 Edinburgh series but the proportion of moderately anemic infants (61 to 70 per cent of hemoglobin) has risen by 10 per cent in Edinburgh as compared with the Aberdeen figure. Eighty-three per cent of the Edinburgh infants and 87 per cent of the Aberdeen infants have a hemoglobin level of less than 80 per cent. After three years of war there has been no deterioration in hemoglobin levels, but anemia is still common. Any advantage which the Edinburgh has over the Aberdeen series in infancy appears to be lost during the preschool or the 2 to 5 year period. Thus on

entering school at 5 years the Edinburgh children had an average hemoglobin of 81 per cent compared with an average figure of 87 per cent for the Aberdeen series. Only 9 per cent of 197 school children had hemoglobin levels of 90 per cent. The hemoglobin levels of children reaching school age were slightly lower in the Edinburgh series than in the prewar Aberdeen series. More than half of the children in the Edinburgh series had hemoglobin concentrations below 80 per cent. The frequency and degree of anemia in these school children call for the most careful consideration by both local and national authorities. During the period of active growth and mental development the incidence of anemia should be reduced to the lowest possible level. This can be achieved by the provision of school meals which are appetizing, well balanced and rich in foodstuffs with a high iron content and/or by supplying iron to the children in the form of a tablet or a mixture or incorporating it in some universally eaten food, such as bread.

Plasma Protein Storage.—To determine plasma protein storage Beattie and Collard studied the effects of plasma transfusions on hepatectomized and anesthetized cats and of varying protein concentrations in the perfusing fluid in perfused isolated liver. After repeated transfusions with plasma of a protein content lower than that of the animal's blood, the plasma protein rose significantly in 4 of the 5 animals, and the rise in 1 was of doubtful significance. Four animals lost the major portion of the transfused fluid from the circulation. One animal lost about half the transfused fluid. The plasma protein added to the blood was retained in the circulation in 2 animals and considerable fractions of it left the circulation in the others. Presumably the greater part of this "lost" protein entered the protein stores. Retention of plasma protein in the circulation may be accomplished by increasing the concentration to a much higher level and by expanding the blood volume. The isolated liver experiments show clearly that the liver can mobilize and throw into the perfusing fluid quantities of plasma protein. The stimulus for this production is obviously the low plasma protein concentration of the perfusing fluid. There was also a correlation between the degree of "hypoproteinemia" and the rate of plasma protein production. When plasma was added to the perfusing fluid about one hour after the experiment had begun the results obtained seemed to depend partly on the state of the reserves and partly on the concentration of protein in the perfusing fluid. There can be no doubt that the liver is a "store" for plasma protein, but to determine if it was the only store hepatectomized animals were prepared and after variable periods given plasma. Two animals showed no change in total plasma proteins before they were given a transfusion, seventy minutes after the transfusion 1 showed an appreciable loss of protein out of the circulation, 1 lost a greater amount in forty minutes and 1 had lost some protein before transfusion and continued to lose an even greater quantity afterward. This may suggest a movement of protein into other stores, but they are not as convincing as evidence of movement from such stores into the blood. Such evidence is provided by 2 cats, in 1 over a period of thirty minutes while blood dilution was proceeding, the total plasma protein was raised by a small but significant amount, and in 1 over a period of forty-five minutes while blood dilution was proceeding, the total plasma protein was raised by 11 per cent over the expected value. In the first animal the addition of protein to the circulation continued after a plasma transfusion at about the same rate as before transfusion. The evidence suggests that plasma protein leaves the blood stream in hepatectomized animals in quantities greater than might reasonably be required for normal metabolism and, conversely, these animals seem to possess some source of plasma protein other than the liver. Whether all body cells can contribute protein to the blood stream with the facility with which they can apparently withdraw it has yet to be decided.

Pathogenesis of Hypochromic Anemia Following Gastric Resection.—Attention has frequently been called to the frequent occurrence of anemia particularly hypochromic anemia following resection of the stomach for gastroduodenal ulcer. It was assumed that iron deficiency was the cause. According to Hemmeler anemia due to iron deficiency following gastric resection can arise (1) from a deficiency of hydrochloric acid in the stomach. Study of the gastric juice of patients who had stomach resection revealed achylia in from 80 to 95 per cent of the cases reported by various authors. Anemia due to iron deficiency may also be due (2) to too rapid gastric passage of the alimentary mass so that the alimentary iron has not sufficient time to become transformed into an absorbable ionized form. It may be due (3) to the fact that the alimentary mass no longer passes into the duodenum, the site of the assimilation of iron. The author studied these factors with the aid of absorption curves for iron. His investigations reveal that the anacidity or hypoacidity of the gastric juice diminishes the ionization of the alimentary iron which is indispensable for iron absorption. The accelerated gastric passage of the alimentary mass likewise plays a part, because the iron, even in the presence of hydrochloric acid does not have the time to become ionized. The fact that the food does not pass the duodenum, the usual site of iron resorption, is of no importance in the pathogenesis of anemia following gastric resection because ionized iron can be absorbed below the duodenum. Occurrence of hypochromic anemia after gastric resection can be prevented by administration of iron as soon as the serum content of iron shows diminution.

Late Primary Tuberculous Infection.—According to Löffler the less rapid spread of tuberculosis in the population has delayed the primary infection of many persons into adulthood. In Switzerland the primary infection of adults follows the same course as in children. It presents no sharply outlined symptomatology but rather a heterogeneous picture. Many primary infections run their course unobserved, only a small number cause clinical manifestations. Some cases exhibit only roentgenologic changes, others appear as febrile conditions with many possible diagnostic explanations. In the presence of an obscure febrile condition a primary infection should be thought of. The clinical symptoms of erythema nodosum (with or without Poncet's rheumatism and phlyctenae) and of exudative pleurisy of adults, particularly of young adults, are often a typical expression of a primary infection. Tuberculous infiltrates of adults represent particularly typical manifestations of primary infection rather than of secondary infiltrations or of early infiltrates. They are of exogenic origin and call for isolation and examination of persons in their environment. Today it is necessary to prove secondary infiltrations, whereas until recently it was necessary to prove primary infiltration. The demonstration of tuberculous exposure supports a suspected diagnosis. Intestinal primary infection must be considered in some cases, although it is rare. The frequent observation of primary infection in military service involves no decisive changes in insurance compensation because when acute extensive dissemina-

tion, pleurisy and erythema nodosum occurred during service or shortly thereafter compensation was granted on the basis of the principle of contemporaneity

Late Primary Tuberculosis and Its Early Evolution—Uehlinger points out that the gradual increase in late primary infections is a result of the gradual decrease in the tuberculous involvement in children. On the basis of postmortem observations in the army, evidence of tuberculous infection can be expected in approximately 50 per cent of the age groups between 20 and 55 years. The importance of late primary tuberculous infection is proved by the fact that, of 72 fatal cases of military and meningeal tuberculosis observed from 1939 to 1941, 60 could be traced to a late primary infection. In contradistinction to postmortem studies, the clinical diagnosis of a late primary tuberculous infection is extremely difficult. The majority (about two thirds) of late primary infections pursue a silent course. Only the postprimary hematogenic and canalicular dissemination of the infection generally leads to clinical manifestations. The most frequent forms of benign, hematogenic early evolution are erythema nodosum and exudative pleurisy, the most frequent malignant form is the progressive protracted dissemination with terminal tuberculous meningitis and military tuberculosis. The source of dissemination is frequently the cavernous breakdown of the primary infiltrate or of a tracheobronchial lymph node perforating into a bronchus. Early malignant evolution of a late primary pulmonary infection must be suspected in the presence of progressive loss of weight, prolonged acceleration of the sedimentation rate, progressive leukopenia with lymphopenia, tachycardia, persistence or greatly retarded absorption of the primary infiltrate, and recurrent febrile bacillemia. Primary infection during adolescence has a comparatively high mortality, because at this time of life there is a predisposition to hematogenous dissemination. High mortality rates are to be expected if late primary infection becomes frequent among a population with a low index of infection. Late primary infections require careful supervision. They suggest the presence of persons with open tuberculosis in the environment.

Late Primary Tuberculosis and Its Development—Of Leitner's 48 patients with late primary infection, 37 complained of fatigue, 16 had cough, 2 expectoration and 33 fever. Sensitivity to tuberculin was pronounced in all. Erythema nodosum was observed in almost one third. While erythema nodosum is not a specific tuberculous lesion, it is seen in the majority of cases. The frequency of erythema nodosum during the primary infection and the pronounced tuberculin sensitivity indicate early development of an intense allergy. Erythema nodosum is probably to be regarded as an allergic reaction. The author differentiates primary infection into (1) a clinically, as well as roentgenologically, latent type recognizable only by the fact that the tuberculin reaction becomes positive, (2) a type clinically latent but with a positive roentgen picture, (3) a type with clinical and roentgenologic manifestations resembling an acute infectious disease and (4) a type with clinical signs but atypical roentgen picture. This last type can be recognized only by the positive tuberculin reaction. The author gained the impression that allergy is usually most pronounced shortly after primary infection. As regards immunity he believes that there is practically no superinfection during the biologic activity of tuberculosis recognizable by the positive tuberculin reaction. The author stresses the advantages of tuberculin tests in large groups (universities, armed forces, occupational schools and factories). It is simple, reveals sources of infection and makes possible early treatment.

Hyperplasia of the Endometrium T. S. Cullen—p. 1

*Chorea in Pregnancy Vitamin B₆ Therapy S. Rabin and H. Duek—p. 12

Chorea in Pregnancy—Rabin and Duek direct attention to the therapeutic value of vitamin B₆ in chorea of pregnancy. They believe that chorea of pregnancy and chorea minor have a common etiology, namely avitaminosis B₆, and that the etiologic therapy in either type consists of administration of vitamin B₆. A primipara aged 19 reported to the hospital during the second month of pregnancy complaining of vomiting.

Emesis was controlled by endocrine therapy. Shortly afterward chorea developed. The treatment consisted in intramuscular injections of 50 mg of pyridoxine given daily for a week and every other day for another week. The total number of injections was ten. The patient was given a diet rich in vitamins. Chorea was rapidly and permanently controlled. The appetite of the patient and her general condition rapidly improved.

Arteriography in Bone Lesions—Lopez Arenal advocates injection of from 10 to 20 cc of a 35 per cent solution of sodium iodide. This substance produces no changes in the vascular endothelium as demonstrated by surgical interventions. Arteriography is of diagnostic value in all bone lesions. To facilitate the exact diagnosis it is important to study the collateral circulation. In benign bone tumors the collateral circulation shows no alteration either in caliber, direction or form of the main vessel, although occasionally the vessel becomes slightly displaced by the tumor. In malignant tumors, particularly sarcomas, the collateral circulation always shows abnormal increase, the vascular net is complicated, branches cross aimlessly without any arrangement, newly formed vessels of irregular distribution course in all directions and there are vessels which supply the tumor. Veritable pools of blood exist in telangiectatic tumors and make the roentgenogram appear cloudy. The appearance and extent of the collateral circulation are the chief guide in the differential diagnosis between neoplastic and non-neoplastic bone lesions and between benign and malignant bone tumors. Arteriography is also a valuable aid in the control of the roentgen irradiation of bone tumors.

Cerebral Disturbances in Aviators During Acrobatic Flights—Pescador mentions the various aspects of acceleration disease and emphasizes that a cerebellar component exists in the disturbances that develop during acrobatic flights. This cerebellar component is manifested by static changes, by mild disturbances in walking and in coordination, by tremor and by hypermetria. In animal experiments changes become evident which indicate disturbances in the inferior nuclei demonstrated by the abolishment of certain statokinetic reflexes. It is suggested that the blood perfusion of the dentate nucleus, which is the weakest point in the cerebellar economy, assumes a decisive role in the pathogenesis.

*Transmission of Leprosy by Fleas Some Observations G. Muñoz Rivas—p. 635

Dementia Paralytica, Tabes and Diabetes Insipidus A. Hernandez—p. 680

Transmission of Leprosy by Fleas—Muñoz Rivas found that when fleas of the type *Pulex irritans* and *Pulex canis* bite patients with leprosy they suck up lepra bacilli which will survive for more than twenty-six hours in the digestive tract of these insects. The stomach of larvae fed on dejecta of adult fleas biting patients with leprosy contain acid alcohol resistant bacilli in 21 per cent of the cases. The stomach of larvae fed on infected leprosy food contain lepra bacilli in 100 per cent of the cases. The stomach of larvae from fleas captured in the rooms of patients with leprosy or which were left in contact with earth from the rooms of these patients contain acid alcohol resistant bacteria morphologically identical with lepra bacilli in 75 per cent of the cases. The author concludes that fleas transmit leprosy. Extermination of fleas should be a part of the campaign against leprosy.

Book Notices

Sulfanilamide and Related Compounds in General Practice. By Wesley W. Spink, M.D., F.A.C.P., Associate Professor of Medicine, University of Minnesota Medical School, Minneapolis. Second edition. Cloth. Price \$3. Pp. 374 with illustrations. Chicago: Year Book Publishers, Inc. 1942.

A subject of the greatest interest to all practitioners of medicine is the use of the various sulfonamide compounds in the treatment of infections. Indeed, no aspect of medicine has attracted wider attention during the past few years. In this edition of Dr. Spink's monograph there is presented in a simple, direct and clear style a summary of sulfonamide therapy which should be read by every student of the subject and every practitioner of medicine who uses these important therapeutic agents. The text shows a sense of critical method which is invaluable to the reader, and many of the case reports which are based on the author's personal experience are illustrated by good charts. Dr. Spink has done a splendid piece of work and the medical profession is indeed fortunate to have such an authoritative and up to date monograph on the sulfonamides available as a guide to treatment.

How to Be Fit. By Robert Kipling, Director of the Gymnasium, Associate Professor of Physical Education, Yale University, New Haven. Foreword by John Kieran. Cloth. Price \$2. Pp. 131 with illustrations. New Haven: Yale University Press, 1942.

The book is a well written, well edited collection of exercises directed toward physical development. The purpose of the exercises is to work all muscles of the body including some that are little used. The exercises do not call for sudden strain nor do they tax the body unduly. There are two sets of lessons. Each lesson is composed of eight exercises, with excellent illustrations of each. The first set of lessons numbers fifteen and is designed for general use of old and young. Any one who plays golf or tennis or does gardening can do them. The second set of five lessons is a sort of "postgraduate" course, to be used on completion of the first set and only by the young and strenuous who wish further development. The book is well worth while for use in gymnasiums, schools, Y. M. C. A.'s and colleges. The author is an authority on the subject, having been the director of gymnasiums and swimming coach at Yale for twenty-five years. The book is the result of his experience.

Manual of Dermatology. By Donald M. Pillsbury, M.D., Marlon B. Sulzberger, M.D., and Clarence S. Livingood, M.D., Military Medical Manuals. Issued under the auspices of the Committee on Medicine of the Division of Medical Sciences of the National Research Council. Cloth. Price \$2. Pp. 421 with 109 illustrations. Philadelphia & London: W. B. Saunders Company, 1942.

As the material in this manual is designed for the use of medical officers, the text concerns itself only with the management of the dermatoses commonly encountered in the armed forces. Consideration is not given to rare or obscure dermatoses or to those affecting particularly women, children or the aged.

The authors have designed a textbook which will be most useful for the diagnosis and treatment of the vast majority of the cutaneous disorders encountered. The early chapters cover the general considerations of diagnosis, with due emphasis on the history and the clinical findings with regard to primary and secondary lesions and the distribution of the lesions. Then follows a chapter which deals with the sites commonly involved in a number of dermatoses. This material is presented chiefly by means of fourteen full page illustrations which demonstrate graphically the topographic tendencies of some sixteen dermatoses and twenty-seven types of involvement of the mucous membranes.

The common disorders are then considered individually from the standpoints of clinical findings, differential diagnosis and treatment. These descriptions are concise but contain a maximum of information. A particularly valuable feature in this section is the use of numerous inserts which emphasize important fundamental features in the various diseases and which furnish guideposts designed to avoid common errors in diagnosis and treatment.

The material dealing with treatment includes a chapter on the general principles of local treatment and consideration of simplified and of extended therapy, the latter for use in hospital or sick bay. In addition an appendix furnishes a formulary of eighty-two prescriptions of tested merit.

All the clinical illustrations are grouped in one section of seventy-eight pages; these have been well selected, and salient diagnostic features are pointed out in the legends.

The authors have used their material in so ingenious a manner that a vast amount of information has been compiled in a small space, and the manual should have a great appeal for physicians both in military and in civil practice of medicine.

Blenorragia y sulfamidas. Blenorragia. Nociones generales de diagnóstico y tratamiento actual. Sulfamidas. Estudio clínico experimental. Sulfamidoterapia en la blenorragia. Por Guillermo Jacaprazo, profesor adjunto de la facultad de ciencias médicas de Buenos Aires. Tesis de profesorado. Paper. Pp. 562 with illustrations. Buenos Aires: Imprenta Ferrari Hnos., 1941.

The subject matter consists chiefly of the diagnosis and modern treatment of gonorrhea, with clinical and experimental data. Of great interest are those sulfonamide compounds not generally used in the United States such as uliron, neo uliron, albucid and rodillone. With uliron Scherber and independently, Lohe and his co-workers are quoted as claiming 75 per cent cures in 75 and 98 cases respectively. But the author obtained in 54 cases only 19 cures. In 11 per cent of these prostatitis and epididymitis developed during treatment. With albucid the author quotes von Kennell as curing 86.5 per cent of 200 cases and St. Wolfran of Vienna as curing 98 per cent of 81 cases treated. The author himself, however, finds this drug less effective than sulfapyridine, even though better tolerated. Rodillone has been considered of value by Heitz-Boyer. Durel, however, obtained only 20 per cent cures and felt that the compounds' greatest value was in subacute cases. Saby stressed the early use of rodillone. If there was no response in a week the drug was discontinued.

Illustrations showing the gross and microscopic lesions in intoxication with these compounds are excellent. Experiments were carried out on a series of 55 rats to demonstrate lesions of the gastrointestinal tract and other organs. The changes in the stomach varied from simple erosion to ulcerative necrosis. Chronic intoxication was manifested as chronic inflammation. No lesions were found in the control animals or in animals receiving subtoxic dosage. Sulfapyridine brought about the severest reaction. In decreasing severity red prontosil, uliron and white prontosil produced superficial lesions. No lesions occurred with albucid, septazine, sulfathiazole and neo uliron. The author concludes that sulfapyridine is contraindicated for patients with inflammatory and ulcerative gastric lesions.

Normal and pathologic tissue cultures containing a 1 per cent concentration of the various sulfonamide compounds were studied. The sulfonamides did not produce definite cytolysis or inhibit the growth of either the normal or the pathologic (fuscellular sarcoma of the rat) tissue in this concentration. The monograph is a complete treatment of the subject up to and including the introduction of sulfathiazole.

This Is My Life. By Agnes Hunt, D.B.E., R.R.C. Foreword by Morris Bishop. Cloth. Price \$2.90. Pp. 27 with drawings by Georg T. Hartmann. New York: G. P. Putnam's Sons, 1942.

Agnes Hunt in 1900 founded the first open air orthopedic hospital. The Boschurch Home was then an old farm house in a village in England. In less than forty years the home had become a hospital of more than 300 beds with orthopedic clinics stretching out over eight counties, a staff of after-care nurses and a training college for cripples. By 1901 the stable about the old home had become the plaster room, the coach house the splint shop, the saddle room a bathroom, the cow houses a laundry, and the pigsty, after many vicissitudes, was turned into a sitting room. Nevertheless the home had an attraction for cripples. The author, who was a cripple, was advised to consult Mr. Robert Jones, the great orthopedic surgeon of Liverpool. This day in 1903, she says, was the greatest day of her life, even though it was followed by three months in a "Jones abduction frame." Robert Jones later came to the countryside in consultation and on his way paid a visit to the Boschurch Home.

When no one descended from the train at the stop, the great specialist was found comfortably asleep in the train. Thus Robert Jones became interested in the home and for nearly thirty years thereafter "worked for us and loved us even as we well-migh worshipped him." It was his genius and great spirit which developed this home into a vast hospital, which shortly after Sir Robert's death was named the Robert Jones and Agnes Hunt Orthopedic Hospital. Sir Robert died on Jan. 18, 1933. Agnes Hunt wrote this book to amuse him in his last illness. No doubt Sir Robert was amused by Agnes Hunt's tales of her remarkable mother, whose size, it is said, was equaled only by her iron whims and determinations and who with whirlwind energy "managed family perils, domestics, animals, storms and continents." Mamma Hunt transported her large family to Australia to raise angora goats, only to learn on arrival that no one there had ever seen an angora goat. After difficult years in Australia the family returned to England by way of the United States and decided to start a convalescent home. This book should interest nurses particularly. The dean of Durham, the Rev. C. A. Allington, author of "Poets at Play," offered to refund the purchase price of the book to any one who did not feel happier and better for reading it.

Personal and Community Health. By C. E. Turner. A. M. Sc. D. Dr. P. H. Professor of Biology and Public Health in the Massachusetts Institute of Technology. Cambridge. Sixth edition. Cloth. Price \$3.50. Pp. 652 with 131 illustrations. St. Louis: C. V. Mosby Company, 1942.

This edition of Turner's standard textbook is satisfactory. It follows the conventional textbook arrangement with part one devoted to personal health, part two to community health, appendix A to communicable diseases and appendix B to an evaluation of disinfection methods and materials. The material is sound, well selected and clearly presented. Professor Turner gives perhaps more anatomic basis than most writers on personal and community health. The book covers fully the important questions of health values, nutrition, digestion, oral hygiene, respiration, circulation, excretion, endocrines, special senses, mental hygiene, exercise, body mechanics, foot hygiene, reproduction, heredity, narcotics and stimulants, and responsibility for health maintenance as factors in the individual health. Under community health will be found discussions of disease prevention, communicable diseases, immunity, specific diseases, food control, water supply, waste disposal, ventilation, heat and light, public health administration, maternal and child health, and school and industrial hygiene. There are 127 illustrations in black and white and 4 color plates. There is a good glossary and an adequate index. The book can be recommended for its thoroughness, reliability and clearness.

Her Star in Slight. Mary Carstens in Medical School. By Mildred Foulke Meese. Cloth. Price \$2. Pp. 331 with illustrations by Sandra James. Indianapolis and New York: Bobbs-Merrill Company, 1942.

This is a romantic story of Mary Carstens, who decided while still in high school that she wanted to be a doctor. Mary had lived for many years in an orphanage. Now we see her in medical school, in the sorority house, in the hospital wards as a student and through her internship, graduation in medicine and state board examinations. Mary was in love with young Dr. Peter Kirkland, who after the attack on Pearl Harbor was commissioned a major in the medical corps with the Marines. Fortunately Peter was able to attend Mary's graduation in his uniform before leaving for military duty and they became engaged. Before writing this novel the author visited hospitals, laboratories and classes in medical schools and studied medical records. It has, therefore, some medical background and should interest girls who have an ambition to study medicine.

His Sword. A Tale of the Vikings. By Alfred C. Muller. M.D. Cloth. Price \$2. Pp. 246. Boston: Meador Publishing Company, 1942.

Years ago a sunken ship was discovered near Oeseberg, Norway, which was the grave of King Harold's daughter, Queen Asa of Viken, and her favorite handmaiden, who had been killed in order that she might serve her mistress in Valhalla, as was the custom of those times. This ship is now in a museum in Oslo. The author, a country doctor now 76 years of age, began to write a historical novel based on this discovery, but as he

delted into history it appeared that Queen Asa had done away with her husband and therefore did not deserve the service of a lovely handmaiden in Valhalla or the sacrifice of her life in order to serve the queen. The author then abandoned the strictly historical outline and wrote a fanciful story in which he makes the queen a heroine and spares the life of her handmaiden. The book takes its title from the great sword Sunderer, with which it was believed no brave king could ever lose a battle. When King Erling died he bequeathed the great sword to his young son Ottar, who swore to forge the Northland into a united kingdom. At the same time the tender youth laid the foundation for a psychic inhibition which ardent love for his queen could not overcome. The author shows an insight into human nature throughout the book. His style and choice of words are well adapted to a story of the hardy vikings.

The Making of a Surgeon. A Midwestern Chronicle. By Ernest V. Smith. M.D. D.Sc. F.A.C.S. Cloth. Price \$3. Pp. 344 with illustrations. Fond du Lac, Wis.: Berndt Printing Company, 1942.

At 23 the author decided to study medicine even though it was necessary to work his way through medical school. After graduating in 1907 at the University of Minnesota and without having an internship, he married the girl he had been courting for many years and went into practice in a small town. Four years later he accompanied a patient to the Mayo Clinic, where his former instructor Dr. Louis B. Wilson suggested that he come to the clinic to work for three years, one in pathology, one in internal medicine and one in surgery. "Then," Dr. Wilson said, "you will be a real doctor." The author followed this advice. He established a clinic in Fond du Lac, Wis., in 1916 in partnership with other physicians, three of whom are still there after more than twenty-five years, a period, the author says, longer than any other three doctors have worked together in the same capacity in the history of medicine and surgery. These men are Dr. Oliver M. Layton, Dr. William J. Waldschmidt and the author, also working with them throughout this period as a surgical nurse has been Sister M. Agneta and during the last seven years the author's son, Dr. Ernest V. Smith, Jr. This book is the story of the author's boyhood and of his work later in the profession of medicine. His opinions on medical education and medical practice are sound.

Outline of Histology. Part I. General Histology. Part II. Dental Histology and Embryology. By Margaret M. Hoskins. Ph.D. and Gertrude Bevelander. Ph.D. Departments of Anatomy, College of Dentistry and the Graduate School of Arts and Science, New York University, New York. Paper. Price \$2.50. Pp. 179 with 80 illustrations. 112 with 56 illustrations. St. Louis: C. V. Mosby Company, 1942.

This outline of histology is apparently meant as a student aid. Such student aids have, in our opinion, no pedagogical value unless made by the students themselves. A prepared outline does not offer the student an opportunity to train himself in scientific thinking and cannot replace a textbook. But some teachers do not agree with this idea and approve of read-made outlines. They demand, however, that they be short and clear. Both of these qualities are lacking in this book. The text is often inaccurate, and the efforts to explain too much in too brief a span are confusing. The diagrammatic illustrations will not help to give the student much histologic insight. The extensive section on dental histology is somewhat better than the rest of the book. This, however, does not justify the superficial treatment of the outline. It is inferior to other textbooks of dental histology which are available. There is no index.

Fundamentals of Psychiatry. By Edward A. Strecker. M.D. Sc.D. F.A.C.P. Professor of Psychiatry and Chairman of the Department of Undergraduate School of Medicine, University of Pennsylvania. Philadelphia. Cloth. Price \$3. Pp. 201 with 15 illustrations. Philadelphia: Montreal & London: J. B. Lippincott Company, 1942.

This little manual is a useful and accurate summary of psychiatry as it is seen through the eyes of a leading specialist. The chapter headings are the usual ones, on etiology, classification of mental diseases, methods of examination and the various types of psychoses. Part of a chapter is devoted to the psychoneuroses, and there is a short chapter devoted to defectives. About seven pages are devoted to some of the neuropsychiatric problems of war. The book is systematic and has a number of good illustrative case histories. It is remarkably complete for its small size.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

AIR EMBOLISM

To the Editor—A discussion arose as to what consequences might commonly be expected to follow accidental injection of air into the venous circulation, incident to intravenous therapy. Are there any records as to the approximate amount that has been introduced without developing important reaction?

Captain M C, A U S

ANSWER—The danger of air embolism during an intravenous drip must be minimal, since 5 to 10 cc of air has been injected rapidly in man without producing clinical symptoms. The entrance of sufficient amounts of air to produce clinical symptoms requires a gaping of the injured vein and a definite sucking action toward the heart. These factors are present at the large veins of the neck and at the root of the arm (internal and external jugular, subclavian and axillary veins). These veins are fixed by fascial coverings and cannot readily collapse. The placental veins following childbirth and the pulmonary veins, when surrounded by scar tissue, which prevents collapse, are particularly predisposed to permit the entrance and transport of air.

In the case of venous air embolism, a characteristic hissing sound is heard followed by a peculiar churning of the heart. This sound may hardly be heard with the stethoscope but occasionally can be heard at a considerable distance from the patient. When air enters the right side of the heart it is pressed, in the shape of foam or large bubbles, into the pulmonary artery. Death may occur through asphyxia just as in thromboembolism or dyspnea, cyanosis and tightness of the chest develops, all of which may disappear if the air bubbles are not too obstructive. If the entrance of air is through the pulmonary veins following pleural punctures, pneumothorax or operations on the lung, the air embolus obstructs segments of the arterial tree. The tongue may show pallor, air bubbles can be seen in the retina. Petechial hemorrhages in the skin occur. Blindness, dizziness and convulsions may be present. The administration of 100 per cent of oxygen with a Boothby mask may save life or minimize permanent damage by absorbing the nitrogen bubbles from the vascular tree.

HISTIDINE AND MUCOUS SECRETION IN PEPTIC ULCER

To the Editor—On page 345 of your book *Selected Questions and Answers* it is stated that Lenormand (*Presse med* 41:1141 [July 19] 1933) expressed his belief that the beneficial effect of histidine therapy in ulcer was due to its action on the vagus autonomic system causing an increased secretion of mucus. Is there available any therapeutic agent with an antihistidine effect, preferably one that specifically neutralizes a supposed (?) excess production of histidine thus causing a decreased secretion of mucus?

H D Coles M D Chicago

ANSWER—There is no evidence to support the view of Lenormand that histidine exerts an effect on the vagus-anatomic system, thereby causing an increased secretion of gastric mucus. Mucus is secreted by the epithelium of the entire surface of the stomach, by the mucoid neck cells of the fundus and by the cardiac and pyloric gland cells. Little is known about the regulation of its secretion, although it is known that mucus is secreted by the resting stomach and that the production of mucus is relatively greatly decreased during the active secretion of hydrochloric acid. In animal experiments, stimulation of the vagus and sympathetic nerves has been shown to result in an increased output of mucus. The injection of epinephrine is followed by secretion of mucus; this secretion is not abolished, however, by the administration of atropine (Portis, S A. *Diseases of Digestive System*, Philadelphia, Lea & Febiger, 1941, p 100).

There have not been any reports to suggest the existence of any therapeutic agent which diminishes the secretion of gastric mucus. Nor does there appear to exist a substance which may presumably neutralize histidine. Indeed, it has been demonstrated fairly conclusively that histidine does not exert any effect on the volume and acidity of gastric secretion (Chang, Hsiao-Ch'ien. *Proc Soc Exper Biol & Med* 37:155 [Oct.] 1937; Goodman, L S, and Bearg, P A. *The Action of Histidine on*

the Gastrointestinal Tract, *Am J Digest Dis* 5:117 [April] 1938; Atkinson A J, and Ivy, A C. *Further Attempts at Achlorhydria*, *ibid* 5:30 [March] 1938).

It may be stated also that the supposed beneficial effect of histidine in the treatment of gastroduodenal ulcer has not been observed in numerous well controlled experimental and clinical studies. Stalker, Bollman and Mann (*Am J Digest Dis & Nutrition* 3:822 [Jan] 1937) and Sandweiss, Saltzstein and Glazer (*ibid* 4:20 [March] 1937), among others, were unable to prevent the development of ulcers in "Mann-Williamson" dogs by the intramuscular injection of histidine. Sandweiss (*THE JOURNAL*, April 25, 1936 p 1452) in a careful clinical study of the problem concluded that the transient symptomatic effects of histidine could be explained entirely on the basis of a psychotherapeutic response to hypodermic medication given enthusiastically. Finally, no condition is known in which the secretion of mucus is excessive or in which its inhibition would be desirable.

PROBABLE OVARIAN NEOPLASM

To the Editor—A housewife aged 55 complains of intermittent and increasing menorrhagia of one year's duration. Previous to that time she went two to three months without menses on several occasions since the age of 51. She has noticed an increasing size and hardness of the lower part of the abdomen for the past year. Her temperature, pulse and respiration were normal, the blood pressure 230 systolic and 110 diastolic, the weight 149 pounds (68 Kg). She lost about 40 pounds (18 Kg) in the past one and one-half years partly through diet. Pelvic examination reveals a protrusion of the cervix about 1½ inches beyond the vaginal introitus without straining. There is some cornification of the mucous membrane but no ulceration or erosion. The cervical canal is about ½ inch in diameter and a pale, reddish mass about ¼ inch in diameter can be seen attached within the canal to the anterior lip. The uterine isthmus is about 1 inch in diameter and about 2½ inches long. In the right side of the pelvis is a mass about 5 inches in diameter extending into the abdomen to about 1 inch inferior to the umbilicus. The mass is firm, smooth, freely movable and not tender and lies immediately deep to the abdominal wall. It is either a part of the uterine body or is attached to it. In the left side there is another mass which entirely fills this side of the pelvis and extends into the abdomen about 2 inches superior to the left pubic ramus. This mass can be moved but gives the impression of being wedged in the left side of the pelvis. It is firm and rather tender. On its inferior aspect it presents two nodules each about 1 inch in diameter. My diagnoses are hypertension—possibly essential, multiple fibromyomas of the uterus (larger than a four month pregnancy), descensus uteri, cystocele, rectocele and slight urethrocele. However, there are no symptoms suggesting the latter. I should appreciate recommendations as to the handling of this case.

M D Washington

ANSWER—One of the first things to think of in a woman 55 years old who bleeds profusely is a granulosa cell tumor of the ovary. The patient may have this condition even if she has uterine fibroids or other neoplasms. Regardless of whether or not a granulosa cell tumor is present, tumors of the size mentioned, especially in a woman of 55, require prompt treatment. In spite of the patient's hypertension it is not advisable to apply radiation therapy, chiefly because it is highly important to make a correct diagnosis. This can be done only by a laparotomy.

The patient should be put to bed for at least a week, preferably longer, with a view to reducing the blood pressure and building up her resistance as much as possible. All the necessary laboratory tests should be made and she should be given repeated small doses of a sedative such as phenobarbital to help reduce the blood pressure. She may also be given large amounts of vitamin C in addition to a well rounded diet. If the red blood cell count is below normal it should be increased, by transfusion if necessary. Consultation should be had with a physician anesthetist concerning preoperative medication and also the safest anesthetic to use. If possible an internist should be present at the operation, and certainly all paraphernalia and medication should be at hand for the treatment of shock or any other complication. The physician assistants and nurse should be familiar with the surgeon's technic so that there will be a minimum of motions, confusion and delay. It is essential to remove the neoplasm as speedily as possible and with the least amount of trauma. No effort should be made to repair the relaxed vagina. At the time of suturing the cervical stump (if a supravaginal hysterectomy is performed) or closing the vaginal vault (if a total hysterectomy is done) the bladder can be advanced so as to take up part of the vaginal relaxation. A much better procedure is to sew the cervical stump or the vaginal vault to the fascia of the rectus muscles. Anchoring the vaginal vault to the abdominal vault should correct the prolapse. In nearly all cases in which such a suspension is performed, a perineorrhaphy must also be carried out, but in this

case only the abdominal operation should be done and not the vaginal. The shorter the operation and the period of anesthesia, the safer it will be for the patient.

In a case like this it is best to remove the entire uterus and both tubes and ovaries not only because of the strong likelihood of a malignant growth in the ovaries or uterus but also because there is a large polyp or pedunculated, submucous fibroid in the cervical canal.

If the surgeon is not capable of performing a total hysterectomy with ease and rapidity, he should ask some one else, preferably an experienced gynecologist, to do the operation. The patient's life will depend in large measure on the skill of the operation, and she should have the best possible care.

If the vaginal prolapse is present after the abdominal operation, a pessary may be inserted in the vagina or a plastic operation may easily be done under direct infiltration anesthesia a few months after the laparotomy, provided of course the patient's general condition will permit the operation.

PERSISTENT ULNAR NERVE PAIN AFTER CONTUSION

To the Editor—A patient injured his elbow as a result of a fall. He is a carpenter and the handle of the hammer is supposed to have struck the elbow in the course of the fall. About two months ago the ulnar nerve was moved from its original position behind the internal condyle and deposited in a new bed in front of the condyle. This operation was done because of a diagnosis of chromatic neuritis. The patient has continued to have more pain than he had previous to it even after a period of two months. At operation the sheath of the nerve was also dissected free for a space of approximately $1\frac{1}{2}$ inches. The surgeon evidently thought that the trauma had injured the nerve sheath and that there was some constriction that accounted for the pain. The problem which I have to decide is whether or not I have to operate again and transfer the nerve to its original bed. I think it is possible that the new position of the nerve causes it to be stretched unduly and may have something to do with the continuation of the pain. Diathermy and other forms of heat application have not given good results nor has massage.

P H Owens M D Kansas City Mo

ANSWER—On the basis of the information submitted, the only explanation which can be suggested for the pain in the ulnar distribution is that the nerve was contused and the neuralgia is at the point of contusion, although the nerve was probably not divided. There would be nothing gained or lost by restoring the nerve to its original position. If a neuroma cannot be found on exposing the nerve it would probably be better to divide the nerve, on condition that the pain is bad enough to warrant this procedure. If a neuroma can be found, it should be resected and the nerve resutured.

IDENTIFICATION OF RETAINED PLACENTAL TISSUE

To the Editor—Given a case of spontaneous subacute inversion of the uterus a curettage was done to determine the possible retention of placental tissue. Is an obstetrician justified in stating that he can recognize with certainty with the naked eye placental tissue in the form of uterine curettings or must it always be confirmed by microscopic findings of chorionic villi?

M D New York

ANSWER—Placental tissue can usually be determined with the naked eye particularly in the early weeks of pregnancy. A simple way to verify the presence of placental villi is to immerse a portion of the tissue in water. If villi are present they will stand out prominently. At or near term a firm blood clot removed by curet may be mistaken for placental tissue, but by breaking up the clot one may easily determine the true condition. Occasionally a piece of thick decidua is mistaken for a piece of placenta containing villi. In such a case, if the water immersion test does not help, a hand lens almost certainly will. When a curettage is not performed until days or weeks after a miscarriage or full term labor, a hard hemorrhagic piece of tissue is often removed, the contents of which can be determined only by microscopic examination.

INTRANASAL INSULIN ADMINISTRATION

To the Editor—In August 1936 there was an article in *The Journal* regarding the experiments of Ralph H Major M D in the use of intranasal applications of insulin. Please advise me if this experiment was carried further and with what results.

R W Holley M D Appalachia Va

ANSWER—Some 25 patients with diabetes of moderate severity have been treated by intranasal application of insulin and there is no doubt that they can be controlled by this method. It has been abandoned for two reasons. First, it proved to be an expensive method of administration because the doses were necessarily larger than those effective with hypodermic medication. Second, most of the patients after a time grew tired of the frequent nasal spray and prefer to return to subcutaneous administration.

ULTRAVIOLET LAMPS IN SCHOOLS FOR PREVENTION OF INFECTIONS

To the Editor—I should like to ask about the advisability of installing special ultraviolet ray lamps in our centralized school for the prevention of air borne infections. The literature on this subject seems promising but questions have arisen as to whether there would be any harmful effects from the ultraviolet rays such as injury to the eyes or skin cancer.

M D New York

ANSWER—There is not sufficient evidence to sponsor unservedly the use of ultraviolet lamps in schools for the prevention of air borne infections. Nevertheless it is well known that ultraviolet emanations of selected ray lengths are bactericidal at short distances. In the application of this knowledge to school buildings, the installations should be such as to rule out any likelihood of injury to the eyes, skin burns or like hazards.

DISPOSITION OF RADIUM SUPPLY WHILE IN MILITARY SERVICE

To the Editor—If I enter military service I must put away for the duration about 100 mg of radium. I do not wish to keep it around my small home for I have learned that lead or no lead, it darkens film within a few days and I don't wish it near my children. What do you suggest as a means of disposing of it safely for an unpredictable length of time until I return to practice?

M D Missouri

ANSWER—The best disposal of radium during the war is to keep it in use in treatment of the sick. There should be an attempt to make arrangements with a responsible man to store and use the radium in his own practice at the same time getting authority to do so from your insurance company. Caution must be used in choosing a physician who already uses radium and is skilled in its use and care. Someone may be found who needs an extra supply and who would be willing to pay something for its use, at least the insurance premium.

BIOPSY OF PROSTATE THROUGH RECTAL WALL

To the Editor—At a recent meeting of our tumor board we discussed a case in which a suggestive nodule in the prostate was easily accessible to palpation on rectal examination. One physician of some years of experience advised taking a biopsy through the rectal wall stating that the idea that one should not go through the rectal wall was nonsense and on idea which physicians have handed down without foundation. If this is true some of us who expose the prostate through a perineal incision to take such biopsies are making rather hard work out of what could be an easy and minor procedure. I would appreciate an opinion on this subject.

J Robert Rinker M D Fort Worth Texas

ANSWER—A biopsy made through the rectum into the prostate is not good surgery. Such penetration of the bowel can result in infections.

STABILITY OF SOLUTION OF SODIUM SULFATHIAZOLE

To the Editor—Please advise how long solution of sulfathiazole is stable and potent.

J J Johnson Jr M D Las Vegas N M

ANSWER—The solution of sulfathiazole must mean a solution of the sodium salt. Although it is not known how long such a solution will be stable, it is advisable to use only freshly prepared solutions for injection. In alkaline solution the sulfonamides are readily oxidized and may yield toxic products.

ENDOCRINES AND CARCINOMA

To the Editor—Has orchiectomy or diethylstilbestrol proved to be of any value in the treatment of neoplasms other than carcinoma of the prostate?

L A Crowell Jr M D Lincoln N C

ANSWER—The employment of either orchiectomy or diethylstilbestrol in the treatment of carcinoma of the prostate is still on an experimental basis. There is no reason to believe that these procedures are of any use for other types of neoplasms.

VITAMIN A AND COLOR BLINDNESS

To the Editor—In *Queries and Minor Notes* in *The Journal* Nov 28 1942, page 1080, the answer to M D New Mexico relative to color blindness does not mention the two reports of Dunlap and Loken concerning the possible value of vitamin A in treating color blindness (*Science* 95:554 [May 29], 96:251 [Sept 11] 1942). Granted that this is not a completely studied problem perhaps the inquirer would like to know of the references. It seems too bad that the soldier spoken of should lose his chances for advancement if there is any type of treatment available that might possibly be of benefit even though experimental in character. The doses of vitamin A recommended by Dunlap and Loken do not appear to be sufficiently high to fall within a toxic range.

PROGNOSIS IN HYPERTENSION

ROBERT M DALEY, MD
HARRY E UNGERLEIDER, MD
AND
RICHARD S GUBNER, MD
NEW YORK

While the cause of hypertension remains obscure and the treatment unsatisfactory, and its importance as a prime cause of mortality in adult life looms increasingly great there is nevertheless reason for optimism in the near future and even at the present time. Clinical studies have contributed greatly to an increasing understanding of the course of the disease. These have indicated, as has been aptly stated by Riesman,¹ that while hypertension is not conducive to longevity it is compatible with longevity, and it is, therefore, pertinent to inquire into the various factors which determine the outlook in subjects with hypertension. Until now prognosis has been concerned chiefly with estimation of the life expectancy and the eventuality of various serious complications which tend to occur over a period of years in the majority of subjects with persistent elevation of the arterial pressure. Recent investigations have offered new concepts which clarify the physiologic mechanisms in hypertension and which may point the way to therapeutic advances. The advent of several new therapeutic approaches offers real promise that hypertension may be brought under some measure of control and therefore prognosis becomes of great practical importance both as a standard by which to evaluate new therapeutic procedures and also to indicate the proper selection of cases amenable to various forms of therapy.

THE SIGNIFICANCE OF HYPERTENSION

Broadly, hypertension is important for two reasons as an indication of an underlying disease and because of the deleterious effects of the elevated blood pressure itself. It is well recognized today that elevation of the arterial pressure can result from a great variety of causes. These may be classified into five major groups: renal, endocrine and vascular lesions, disease of the central nervous system, and essential hypertension of unknown origin.² The cases of hypertension in which the etiology is known and can be ascribed to renal, endocrine or other organic disease constitute but

a very small fraction of the total number of cases presenting elevated arterial pressure. Nevertheless, careful search should always be made for any condition which may be associated with and contribute to the hypertension, since occasionally spectacular "cures" may attend therapy of an associated disease, as in nephrectomy in certain cases of unilateral renal disease associated with hypertension. Most frequently when hypertension is secondary to some known cause the prognosis is determined largely by the underlying disease and the hypertension plays a secondary role. Hypertension of whatever etiology, however, may occasionally progress to rapidly fatal malignant nephrosclerosis.³

The injurious effects on the vascular system and vital organs have been considered by some to be due at least in part, directly to the hypothetical noxious substance which causes hypertension, the hypertension itself being merely a manifestation of the effect on the arterioles, and it has even been questioned whether hypertension per se has any influence on the development of arteriosclerosis.⁴ However, all the pathologic changes in hypertension can be reasonably explained in accord with present knowledge as resulting directly from the mechanical effects of persistent elevated arterial tension acting on a vulnerable vascular system. Persistent elevation of the arterial pressure produces two important types of vascular lesions which are distinct in their pathogenesis, characteristics and consequences. These two lesions, arteriolar sclerosis and large artery atherosclerosis, are responsible for most of the serious lesions in hypertension. Hypertrophy of the heart likewise may be ascribed directly to the elevated arterial pressure which results in the performance of greatly increased work by the left ventricle in order to maintain its normal output. Even here, however, the development of heart failure most often is due in part to coronary artery disease, which is usually present and which aggravates a relative inadequacy of coronary supply resulting from hypertrophy itself.⁵

Several classifications for the prognostic grading of hypertension have been proposed based on blood pressure levels and reactivity, on biopsy study of the arterioles and on retinal examination.⁶ These studies have helped greatly to clarify many aspects of the course of hypertension. These groupings are based on arteri-

olar changes which depend on the degree of hypertension, in contrast to changes in the large arteries which are quite distinct in pathogenesis from arteriolar disease, being related to the duration rather than to the degree of hypertension. In a very general way there is some parallel in the development of arteriolar sclerosis and arterial atherosclerosis, but this is not regularly the case. Arteriolar disease has important consequences of serious nature, such as malignant nephrosclerosis and cerebral hemorrhage, which may occur quite unpredictably at any time in the course of hypertension owing to rapid and extreme rises in the level of the blood pressure. Ordinarily, however, essential hypertension has a characteristic evolution over a long period, which may vary from ten to fifteen years or longer, with the ultimate development of heart failure, coronary thrombosis or other vascular complications. The mortality from heart failure and degenerative atherosclerotic changes of the large vessels such as the coronary arteries, which result from long-standing duration of hypertension without regard to its degree, is far greater than the mortality from such causes as malignant nephrosclerosis and apoplexy, which can be attributed more directly to a decided elevation of the blood pressure.

It is evident therefore, that an important consideration in prognosis is the proper evaluation of the duration of the hypertension apart from its degree. Since the degenerative atherosclerotic changes may occur in the absence of advanced arteriolar disease, it appears that the grading of hypertension solely by arteriolar changes which indicate the degree and not necessarily the duration of hypertension has certain shortcomings. It is our object to emphasize the duration as a prognostic guide and to consider the methods for evaluating the stage of the disease.

THE BLOOD PRESSURE

If blood pressure studies have certain limitations which should be appreciated, nevertheless in addition to being the means for recognizing that a state of hypertension exists, determination of the blood pressure is of great prognostic value. There has been considerable diversity of opinion regarding the precise level of arterial pressure that constitutes a state of hypertension. In general, more recent opinion has tended to place the upper limit of normal at lower levels, and whereas thirty years ago Janeway and others regarded that values above 160 systolic and 100 diastolic constituted hypertension, today arterial pressure of 140 systolic and 90 diastolic is usually considered the dividing line. The supposed physiologic increase in average blood pressure with age is due largely to the inclusion of cases of hypertension, the prevalence of which increases greatly with advancing age. If cases of obvious hypertension are excluded in computing average blood pressure, it is found that the level of the average blood pressure rises very little with advancing age,⁸ so that old rules of the thumb, such as 100 plus age for systolic level become grossly inaccurate. The arbitrary exclusion of cases with hypertension in computing

average blood pressure is open to criticism, however, on the grounds of the method of selecting the sample. Instead of attempting to determine average values for blood pressure, it might be preferable to ascertain the modal or most frequently observed level of the blood pressure at various ages and establish limits of normal based on significant deviations from the modal value. Probably the best criterion of abnormal blood pressure is that level at which mortality experience exceeds the predicted average mortality of the population.

The comprehensive study made in 1939 by the Joint Committee of the Association of Life Insurance Medical Directors and Actuarial Society of America⁹ demonstrated conclusively that levels of blood pressure above 140 systolic and 90 diastolic are definitely abnormal at any age and that the actual exceeds the expected mortality in rapidly rising ratios for systolic or diastolic values above this level. A finding of extreme interest, which has been noted previously in actuarial studies,¹⁰ is that the mortality varies with the level of the blood pressure at lower levels too, i.e., that the life expectancy in subjects with blood pressure below average values is decidedly better than the life expectancy of the average population and that fewer deaths from cardiovascular disease occur in this group. This was brought out even more strikingly in the recent study of Hunter,¹¹ which showed that with the systolic pressure 22 to 18 mm less than average the ratio of actual to expected number of deaths was only 71 per cent. Each small increment in the blood pressure above this was associated with a progressive increase in the ratio of actual to expected deaths (i.e., decreased life expectancy). These findings suggest that hypertension should not properly be defined by departures from the average pressure but that the lowest arterial pressure compatible with normal physiologic function is the optimal one. Values in excess of the low optimal level impose an increasing strain on the cardiovascular system, even in the range which has always been regarded as "normal," simply because these are the most common levels. Actually, then hypertension merges imperceptibly with "normal" values of the blood pressure and, except for the distinctive changes in the arterioles consequent to extreme elevation of the blood pressure in the malignant phase, hypertension is not a disease entity but merely a condition which places somewhat greater strain on the cardiovascular system than exists in the average person, producing identical but accelerated and accentuated effects. The atherosclerotic changes in the large arteries are in no way qualitatively different in hypertension from the atherosclerosis in the coronary arteries and aorta which develop in the absence of hypertension but the elevated blood pressure accentuates the development of these lesions. Arteriolar sclerosis similar to that observed in hypertension likewise develops in subjects with normal blood pressure, particularly the renal arterioles, but the changes are definitely accentuated in hypertension in relation to its degree.

Apart from the problem as to just what level of arterial pressure constitutes a state of hypertension is

the question of determining the true level of the blood pressure in any one person. The level of the blood pressure fluctuates greatly both in normal subjects and in those with hypertension,¹² and there is an element of sophistry in the mechanical averaging of a number of readings which has little physiologic significance. It is becoming increasingly recognized that subjects whose blood pressure rises to abnormal levels under any circumstances are predisposed to subsequent hypertension,¹³ and several tests employing various pressor stimuli have been devised to measure the reactivity of the blood pressure as an index of potential hypertension. These tests must be employed judiciously, for, while some of the procedures are simple, such as breath holding or immersion of the hand in cold water, meticulous attention to details is required¹⁴ and a basal level must first be attained. In effect the initial blood pressure reading on physical examination may be regarded as a psychic pressor test and has been recognized as having the same significance.¹⁵

The extreme variability in the level of the blood pressure, diastolic as well as systolic, dictates reserve in drawing conclusions from casual blood pressure readings. The variability of the blood pressure when studied by frequent determinations throughout the day,¹⁶ and its lability under the influence of various drugs, has been employed as a prognostic guide and as an index of the suitability of various therapeutic procedures.¹⁷ In the initial stages of hypertension there is a decided variability of hypertension, but, as the initial variable arteriolar spasticity is gradually succeeded by organic changes in the arterioles in the form of hypertrophy of the media and arteriolar sclerosis, arteriolar relaxation becomes less frequent and less complete and the level of the blood pressure tends to become fixed at higher levels. Diurnal variation becomes less pronounced and there is only an incomplete fall in blood pressure toward normal during sleep or after intravenous injection of barbiturates which remove the tonic sympathetic influence and indicate the degree of residual arteriolar spasticity. The fall in blood pressure following inhalation of amyl nitrite has been proposed as a prognostic test of arteriolar reactivity,¹⁸ the pressure falling less in cases of hypertension with organic arteriolar lesions than in those with earlier arteriolar spastic changes. It has been our experience, however, that a transitory sharp fall in the blood pressure may occur even in the cases of advanced hypertension, and we have observed

a drop in pressure to normal levels under the influence of this potent vasodilator in cases of malignant hypertension, and severe hypertension with apoplexy.

Sodium nitrite and carotid sinus pressure may be employed as depressor tests. Overbreathing for a period of two or three minutes with decrease in the blood carbon dioxide content may also be employed as a depressor test and a fall in blood pressure to normal may occur in the earlier stages of hypertension the response being less extreme than with amyl nitrite. Spontaneous falls to normal levels occur very frequently in hypertension and, to quote Ayman,¹⁹ "This occurs even in patients with widespread vascular changes. Fifty-six per cent of 76 unselected, untreated cases exhibited this finding."

The level of the blood pressure and its lability is of undoubted value in interpreting the degree of hypertension and the extent of the arteriolar changes, but it does not give accurate information concerning the duration of the hypertension and the equally important atherosclerotic vascular changes which as already mentioned, are largely responsible for the mortality in hypertension. The progressive increase in mortality with each increment of blood pressure which has shown up consistently in mortality studies is attributable largely to the fact that in a very general way the blood pressure tends to become more elevated with increasing duration of the hypertension. This is by no means the rule, however, and, as stated by Fishberg,²⁰ "In some instances the blood pressure rises rapidly or more often slowly but progressively as the patient is watched for years. On the other hand in very many patients the height of the pressure does not change notably from that found at the first examination even though it is followed for years." The mortality from heart failure and degenerative vascular changes resulting from longstanding hypertension occurs without any necessary relation to its degree. The limitations of blood pressure levels and tests of reactivity, which measure the degree of hypertension and its effect on the arterioles, are therefore evident.

MUSCLE BIOPSY AND RETINAL EXAMINATION

Direct studies of arteriolar involvement are possible by means of pectoral muscle biopsy and retinal examination. Extensive and valuable contributions have been made by Wagener, Keith, Kernohan and their associates at the Mayo Clinic⁶ as well as by others. The classification of hypertension into four prognostic grades, as suggested by Wagener and Keith, based on blood pressure levels and reactivity, pectoral muscle biopsy and particularly retinal findings is well known and has been generally adopted for the prognostic grading of patients with hypertension. It is with no intent to detract from the value of these studies that we reiterate that these criteria establish the degree of arteriolar involvement and that these procedures do not necessarily indicate the degree of equally significant atherosclerotic vascular disease. As stated by Wagener and Keith themselves,⁶ the cases presenting group 1 hypertension in which the findings of retinal examination and pectoral biopsy are minimal "constitute the great majority of the cases with hypertension." It is apparent

again, therefore, that blood pressure studies, retinal examination and other procedures which reflect the degree of arteriolar disease do not serve equally well as criteria of the duration of hypertension and those complications which depend largely on the duration rather than the degree of hypertension, such as cardiac hypertrophy and coronary sclerosis²¹

CARDIAC HYPERTROPHY

Two changes occur regularly with increasing duration of hypertension which can be evaluated objectively and which are serviceable as prognostic guides. Left ventricular hypertrophy and eventually atherosclerotic changes, particularly in the coronary vessels and the aorta, are invariable accompaniments of elevated arterial pressure of long standing. Hypertrophy is related to the degree as well as the duration of hypertension and usually antecedes significant arteriosclerotic changes somewhat.

Hypertrophy of the left ventricle can be determined by means of x-ray study and electrocardiography, which also serve to reveal arteriosclerotic changes in the aorta and coronary arteries. Roentgen examination is of limited value in the early stages of left ventricular hypertrophy for, since hypertrophy is a matter of an increase in thickness of the left ventricular myocardium of a few millimeters, this cannot be discerned even by the most refined x-ray measurements until in a later stage associated enlargement of the left ventricular cavity supervenes. Concentric hypertrophy of the left ventricle may, however, be suggested by an altered shape of the cardiac silhouette with an increased convexity and rounding of the left ventricular curve even though the dimensions of the cardiac shadow may not be measurably increased. Electrocardiographic changes due to coronary disease are well known, but less attention has been paid to the use of the electrocardiogram than the x-ray examinations in detecting hypertrophy. While the association of a characteristic pattern of electrocardiographic changes with hypertrophy of the left ventricle has been noted by many investigators beginning with Einthoven's early observations, specific criteria have not been established. A study was therefore made of a large group of subjects who had been examined in the Equitable Home office with the object of establishing what electrocardiographic changes in conjunction with left axis deviation could be considered indicative of left ventricular hypertrophy. The findings, reported in detail elsewhere,²² indicate that left ventricular hypertrophy may be considered present when left axis deviation is present in association with any of the following abnormalities in the ventricular complex.

- 1 Increase in amplitude of the QRS complex when the sum of the R wave in lead 1 and the S wave in lead 3 is more than 25 mm (25 millivolts), or when the height of the R wave in lead 1 or the S wave in lead 3 individually exceeds 16 mm (16 millivolts)

- 2 Depression of the ST segment in lead 1, even of as slight a degree as 0.5 mm

- 3 Flattening of the T wave below 1 mm amplitude, or other T wave abnormalities in lead 1

²² Gubner R S and Ungerleider H E Electrocardiographic Criteria of Left Ventricular Hypertrophy Factors Determining the Evolution of the Electrocardiographic Pattern read before the eighteenth scientific session of the American Heart Association June 5 1942

Applying these electrocardiographic criteria, as well as x-ray evidence of left ventricular hypertrophy and aortic widening, to 100 cases of advanced hypertensive heart disease, it was found that 90 per cent showed some evidence of left ventricular hypertrophy or arteriosclerosis of the aorta or coronary vessels in the electrocardiogram or the roentgenogram. The electrocardiogram was found to provide the most sensitive single criterion for detecting left ventricular hypertrophy, being more valuable than roentgen findings.

In order to test the thesis that mortality is higher with increasing duration of the hypertensive disease, as revealed by electrocardiographic abnormalities indicative of hypertrophy, a mortality study according to electrocardiographic findings was carried out on 424 insurance applicants with hypertension.²³ The cases were divided into 4 groups: (1) normal electrocardiogram, (2) borderline electrocardiographic changes, (3) pattern of left ventricular hypertrophy, (4) electrocardiographic changes indicative of myocardial disease with or without a pattern of hypertrophy.

It was found that there was a distinct increase in mortality with progression in the electrocardiogram toward an abnormal pattern, the ratio of actual to expected mortality in the respective groups being 186 per cent, 269 per cent, 344 per cent and 375 per cent, as compared with a normal ratio of 100 per cent. This increase was only in slight part attributable to differences in blood pressure, since there was little variation in the different groups. Adjustment for slight increase in the blood pressure still left a considerable increase in the mortality ratios in the successive groups. There was a relative homogeneity of body build and age also in the different groups, so that the increment in mortality must be considered as correlated with the electrocardiographic findings used as a basis for the classification of the groups.

The results of this study indicate that the stage of the hypertensive disease as determined by electrocardiographic evidence of left ventricular hypertrophy, employing criteria established, is an important consideration in the evaluation of prognosis. Since the electrocardiogram was normal in only 44 per cent of all subjects with hypertension, it would appear desirable to take electrocardiograms routinely in cases of hypertension. The group consisted of insurance applicants, most of whom had no symptoms and were unaware of the presence of elevated blood pressure. Among patients with symptoms undoubtedly even a greater number would show electrocardiographic abnormalities.

ARTERIAL ATHEROSCLEROSIS

The electrocardiogram is of value not only in revealing the presence of hypertrophy but also as an indication of coronary artery sclerosis. Roentgen examination too is useful in demonstrating sclerotic changes of the aorta. Atherosclerosis of the aorta is of greater significance than arteriosclerosis of the peripheral arteries, since it is more closely associated with coronary artery disease. The roentgen findings in arteriosclerosis of the aorta are quite characteristic, consisting of elongation, tortuosity, increased density and calcification, most often in the transverse and descending aortic arch, with diminished pulsation in this region. The ascending aorta is not so regularly involved by arterio-

²³ Daley R M Ungerleider H E and Gubner R S Prognosis and Insurability of Hypertension with Particular Reference to the Electrocardiogram *Proc A Life Insur M Dir America* 28 18, 1941

sclerosis, although it may become somewhat dilated, perhaps to act as a larger reservoir in consequence of the diminished elasticity of the remainder of the aorta. The systolic murmur over the aortic area which is frequently present in subjects with hypertension and arteriosclerosis is not necessarily due to sclerotic changes in the aortic valve or ascending aorta but may be due to dilatation of the ascending arch, which often accompanies arteriosclerosis of the aorta. Another finding occasionally observed on physical examination is a prominent pulsation of the right carotid artery due to buckling and kinking as a result of elongation of the aorta. This may be mistaken for an aneurysm. Widening of the pulse pressure with an elevated systolic and relatively normal diastolic pressure is also indicative of arteriosclerosis of the aorta, and this is not infrequently observed in cases of advanced hypertensive heart disease, the diastolic level falling as aortic elasticity diminishes. Arterial pulse wave velocity, as determined by simultaneous carotid and femoral sphygmograms, is characteristically increased.

One of the simplest and most useful criteria to evaluate abnormalities of the aorta is the measurement recently proposed by Sheridan,²⁴ i.e., the transverse diameter of the frontal aortic silhouette (vascular pedicle) in relation to standards of height and weight as employed in predicting the transverse diameter of the heart, a small correction being necessary for age. This does not distinguish dilatation from arteriosclerosis since increase in the diameter of the vascular pedicle can result from dilatation or tortuosity of the aortic arch, but it does indicate whether the aorta is normal or abnormal.

Analysis of teleroentgenograms in 100 cases with advanced hypertensive heart disease showed a significant increase in the aortic arch transverse diameter, i.e., values exceeding 10 per cent above the predicted, in 54 per cent of cases. Evidence of arteriosclerosis of the aorta was present as frequently as enlargement of the cardiac shadow. Definite arteriosclerotic changes may be present in the absence of any evidence of left ventricular enlargement, and in the series studied the roentgenogram indicated arteriosclerosis and/or cardiac enlargement in 78 per cent of cases. Roentgen examination, therefore, just as electrocardiography is a valuable prognostic guide in adducing evidence regarding the state of the cardiovascular system. It may be mentioned again that definite cardiac enlargement and atherosclerosis of the aorta and coronary arteries may exist in the presence of an arterial pressure which is only moderately elevated and labile and which indeed at times may fall spontaneously to normal values, even though hypertension may be of long-standing duration. The state of the arterioles as revealed by blood pressure levels and reactivity and retinal examination is, therefore, only part of the picture, and investigation for cardiac enlargement and significant atherosclerotic changes by means of physical examination, electrocardiography and roentgen study are essential for evaluating prognosis.

RENAL INVOLVEMENT IN HYPERTENSION

Examination of the urine is of little value as an adjuvant in interpreting high blood pressure, except to distinguish those cases due to glomerulonephritis

or other renal disease. Albuminuria occurs in a comparatively small proportion of cases of hypertension and, while severe albuminuria is often a poor prognostic omen, there is no correlation between albuminuria and the course of hypertensive disease. Impairment in renal function does not occur until relatively late when severe arteriolar sclerosis has led to widespread atrophy of the renal parenchyma. Impairment of the concentrating power, which is a sensitive test of renal tubular function, occurs earlier than a decrease in the urea clearance which tends to be maintained by a relative increase in the glomerular filtration fraction resulting from efferent glomerular arteriolar constriction.²⁵ In malignant nephrosclerosis the severe arteriolar necrotic lesions in the kidneys cause rapid deterioration of renal structural integrity and function, and uremia is usually a prominent part of the clinical picture. In uncomplicated essential hypertension, however, only a small fraction of cases, varying in different studies from 1 to 7 per cent, progress to renal insufficiency.²⁶

In the past few years there has been an attempt to identify essential hypertension with experimental hypertension produced by renal ischemia.² The renal blood flow is usually reduced in hypertension, but there is no proof that this is the cause rather than the effect of the circulatory changes. Investigation of the kidneys should always be made in the presence of hypertension for many cases have been reported with spectacular cures following nephrectomy in cases of unilateral renal disease, such as atrophic pyelonephritis.²⁸ Enthusiasm should be tempered, however, by Allen's estimate that a renal lesion responsible for hypertension can be demonstrated less than once in 300 cases,²⁹ and by the careful study made by Chasis and Redish³⁰ which failed to disclose evidence of unilateral renal ischemia or correlation between structural abnormalities and renal function in a series of 21 unselected cases with hypertension.

It has been observed that hypertension seldom develops in cases with unilateral renal disease unless there previously exists a predisposition to hypertension.¹ In the frequent cases in which unilateral renal disease or hypertension secondary to glomerulonephritis or any cause progresses to the malignant phase of arteriolar necrosis, it may be assumed that there is a high constitutional predisposition to hypertension, with increased arteriolar reactivity which reacts excessively to the pressor substance leading to extreme hypertension with accelerated arteriolar changes.

OTHER FACTORS IN PROGNOSIS

An imposing array of studies all attest a strong hereditary tendency in hypertension,³² and it has been suggested that hypertension is transmitted as a mendelian characteristic. Among young subjects with a family history of hypertension a high incidence of potential hypertension has been demonstrated employing the cold pressor test.³³ It has been observed that succeeding generations in hypertensive families tend to have more severe grades of hypertension and at earlier ages than the previous generation.³⁴

The age at which hypertension develops appears to influence its course. Just as with diabetes hypertension developing in middle and older ages is less often severe and progresses slowly, with the development of atherosclerotic vascular changes. In earlier life hypertension tends to run a more rapid course, often terminating in malignant nephrosclerosis, whereas this occurs less frequently beyond the fifth decade. Apparently the strong constitutional predisposition to hypertension which causes it to develop earlier in life carries with it a greatly increased arteriolar reactivity producing an exaggerated reaction to the as yet unknown pressor agent.

The increased incidence of hypertension in the white race has frequently been noted particularly in comparison to the relative freedom from hypertension among groups leading a more primitive existence and many have therefore regarded hypertension as a consequence in large measure of civilized life. Of interest in this regard is the very low incidence of hypertension among native African Negroes,³⁵ whereas in urban areas in the United States the incidence of hypertension among Negroes greatly exceeds that among the white population and runs a more rapid and severe course.³⁶

The constitutional type of the hypertensive subject is usually described as of hypersthenic habitus with a tendency to obesity. Hypertension occurs frequently in persons of normal or even slender build, but it is true that it is more frequently associated with obesity and the mortality experience when hypertension and obesity are associated is greater than the additive mortality of the two impairments individually.³⁷ A question of some practical importance is whether the obesity and hypertension are both the result of a constitutional tendency or whether elevation of the blood pressure can be more directly ascribed, at least in part, to overweight. There is some evidence for the latter view, and loss of excess weight is a rational therapeutic procedure in hypertension.

While hypertension occurs with somewhat greater frequency in females, the course, as has been repeatedly observed in clinical studies, is more benign.³⁸ Malignant

hypertension develops much more frequently among males, atherosclerotic complications too, such as coronary occlusion, are likewise relatively less frequent among females. Atherosclerosis, as is well known, is observed less frequently in females than males in the absence of hypertension as well. It is remarkable how well some women tolerate severe hypertension for many years without serious complications and indeed frequently with few symptoms. The specific type of hypertension occurring in toxemia of pregnancy has been exhaustively studied and need be referred to only briefly. Attempts have been made to explain the hypertension of pregnancy on a renal basis, but evidence for a renal origin is lacking even more than in the case of essential hypertension, since renal blood flow is increased rather than decreased in preeclamptic toxemia.³⁹

Whatever the etiology may be, preeclamptic toxemia occurs with greater frequency among those predisposed to hypertension, and pregnancy aggravates hypertension leading to toxemia in approximately 50 per cent of cases with preexisting hypertension.⁴⁰ In a relatively high proportion of cases the hypertension initiated or aggravated during pregnancy persists permanently, so that in general it may be stated that pregnancy has a definitely deleterious effect on hypertension.

The association of hypertension with diabetes, which in itself leads to arterial atherosclerosis probably due to the associated hypercholesterolemia, accentuates the development of atherosclerotic lesions. Advanced sclerotic changes in the aorta and coronary arteries are frequently observed at necropsy when the two diseases have been present together and the retinal lesions are likewise severe. Renal lesions, first described by Kimmelstiel,⁴¹ consisting of intracapillary glomerulosclerosis,⁴² renal tubular changes and a nephrotic syndrome due to severe albuminuria, occur in a considerable proportion of cases.

THE EFFECT OF TREATMENT ON PROGNOSIS

Of the innumerable therapeutic measures that have been advocated for hypertension only two have been found effective, potassium thiocyanate⁴³ and surgical procedures on the abdominal sympathetic nervous system.⁴⁴ Very recently an active depressor principle has been isolated from the kidney which is effective in lowering blood pressure in experimental hypertension.

and which has been found promising in a few clinical cases⁴⁵. This work is still in the experimental stage.

The careful observations made by Wagener, Keith and Barker⁶ on a large series followed over many years have been suggested by these authors as a control for other studies. Many of the claims made for various drugs and other measures, subsequently disproved, have been due to a failure to control the study adequately. As previously mentioned, casual readings of the blood pressure are valueless because of the spontaneous fluctuations in the blood pressure. Relief of symptoms is not an accurate guide, since there is a large psychic element and symptoms may be controlled by a large variety of nonspecific measures including placebos⁴⁶. A substantial fall in blood pressure, which may persist for some time, does not always indicate that the improvement is specifically due to the therapy. Thus the claims recently made for tyrosinase⁴⁷ have been shown to be due largely to a nonspecific pyrogenic effect,⁴⁸ the same being true for implantation of renal tissue in which the depressor effect is due to abscess formation⁴⁹. Even though the lowering of the blood pressure is accomplished in a nonspecific manner by these agents, investigation along this line may prove fruitful if high blood pressure can be satisfactorily reduced and maintained at a lower level without injurious effects. The fall in blood pressure following sympathectomy is usually prompt and striking, but a similar fall occurs frequently after any nonspecific abdominal or other operation⁵⁰. The fall in blood pressure following sympathectomy is rarely sustained for more than several months. Nevertheless, carefully controlled studies have shown that in cases presenting severe hypertension and even malignant nephrosclerosis the outlook for life is definitely improved. Recession of severe retinal changes, such as papilledema, hemorrhages and exudates, and improvement in the cardiac status and electrocardiogram, associated with a fall in blood pressure, have been observed in certain cases treated by sympathectomy, thiocyanates and renal extracts. In some instances the employment of two procedures, such as thiocyanates following sympathectomy, has seemed to augment the beneficial effect⁵¹. The outlook, therefore, while as yet grave, offers definite promise.

One cannot expect that any form of therapy, however effective in reducing blood pressure, can beneficially influence organic and irreversible vascular changes. Since the great majority of cases with hypertension are observed rather late in the course of the disease when cardiac and vascular complications have supervened, no specific therapy can hold out much hope at

this stage. The situation is similar to that in diabetes mellitus in which insulin corrects the metabolic derangement but cannot erase the damage that has been done by long years of an unrecognized and untreated condition. As in the case of diabetes concurrently with the development of therapeutic procedures which will effectively lower the blood pressure, and this has not yet been achieved, it will be necessary to educate the public to frequent examinations so that early hypertension and even a predisposition to hypertension will be recognized. It is axiomatic that any treatment is more effective the earlier it is applied, and while no improvement can be expected in a case in which advanced coronary disease with cardiac failure has occurred, or little and temporary response in cases of extreme hypertension with severe arteriolar lesions, the efficacy of any measure will be much greater in earlier stages in which the blood pressure may more readily be reduced to moderate levels and so retard the development of the cardiovascular and other lesions.

CONCLUSIONS

Numerous factors all of which must be considered, determine the prognosis in hypertension. The more important questions to be answered are

- 1 Does a state of hypertension exist and if so what is its degree?
- 2 Can a known cause for the hypertension be found?
- 3 What is the extent of the organic changes in the heart, arteries, arterioles and kidneys?

These among other considerations, including sex, age and the presence of associated conditions, such as diabetes and obesity, are important in estimating the life expectancy and the benefit which may be expected from therapeutic procedures available at the present time.

ABSTRACT OF DISCUSSION

DR BENJAMIN JABLONS, New York. Without definite information regarding life expectancy in individuals affected with hypertension or even the average duration of the disease, one cannot be certain that treatment is of any real value. I have attempted for the past ten years to get such information. By comparing the results obtained with renal extract and other therapies with those furnished by Dr Daley and his co-workers, one may know which of these treatments are of real value. I have attempted to use heart change as an index of prognosis. I have also used it at one time as a basis for the selection of cases to be treated with renal extract. I have found, however, that these changes were not dependable guides. Many patients without any apparent heart changes die early, whereas others with extensive changes survive for long periods. One patient suffering from malignant hypertension with extensive cardiac and retinal changes is still alive and doing well four and one-half years later. He has been treated with renal extract during the greater part of this period, and there has been definite improvement in the heart and eyegrounds, but only statistical studies of untreated cases can properly control such observations. Others have suggested retinal changes as an index of prognosis, but many have heard Dr Scott report improvement in retinopathy with boiled milk injections. One criterion found of great value as an index to prognosis is the urea clearance test. I have also based selection of cases for treatment on this test. If the urea clearance is below 15 per cent of normal I have not attempted to use renal extract, since many such cases may even react unfavorably to this treatment. If the urea clearance, already low progressively, decreases, the outlook is exceedingly grave. Such cases do not respond well to any treatment medical or surgical.

HERNIATED INTERVERTEBRAL DISK

A STUDY OF THE IODIZED OIL COLUMN

THE PROCAINE TEST IN DIFFERENTIAL DIAGNOSIS
FROM REFLECTED SCIATIC PAIN

OLAN R. HYNDMAN, M.D.

ARTHUR STEINDLER, M.D.

AND

JULIUS WOLKIN, M.D.

IOWA CITY

Herniated intervertebral disk, or herniation of the nucleus pulposus, has become a well established syndrome. The lesion is clearly a causal factor for low back pain associated with radiating pain in the sciatic distribution. While the incidence of herniated disks in "sciatic cases" appears to be growing ever larger, there is nevertheless a group of cases in which the back pain and sciatic radiation is related to soft tissue or myofascial injury. Out of the fog of ignorance which has hung for so long over the subject of low back pain these two lights of knowledge have appeared. Each of these two causal factors is productive of definite syndromes and lends itself by the use of proper methods to a high percentage of accurate diagnoses. They indicate prescribed methods of treatment which are rewarded by almost uniformly excellent results. Since in any case of low back pain with sciatic radiation one of these two causal factors is likely to prevail, it is paramount that their respective syndromes and their differentiation be clearly understood.

Herniated disk provokes a syndrome of spinal nerve root compression, and the radiating pain is referred pain associated with the signs and symptoms that attend direct root involvement. We do not believe that herniated disk is the only cause of referred sciatic pain, but it is the most common cause. For example we have seen cases that present a perfect syndrome for a single nerve root compression and in which a diagnosis of herniated disk was mandatory. A herniated disk (concealed or otherwise) was not found to be present, but a decompression of the intervertebral canals of appropriate roots was followed by excellent results. This has been consistent. The causal factor in these cases is not yet so well understood but the pertinent point is that the diagnostician might think more broadly in terms of nerve root compression rather than specifically of herniated disk.

The myofascial syndrome is associated with or provokes a strictly reflex sciatic radiation and hence can be differentiated from referred sciatic radiation.

This paper is a presentation of our experience with these cases, and for convenience it is divided into two parts. Part I is devoted to the cases in which a diagnosis of root compression with radiating pain was made. Herniated disk was the predominant cause and we have elected this as the title of the paper. Special emphasis is placed on the interpretation of the iodized oil film. Having become thoroughly acquainted with the important features of the iodized oil column, we now use the method only in the occasional case in which such a precise confirmation is desired. In addition to the 63 cases reported in this paper we have since done 26 additional laminectomies for herniated intervertebral disk. Of these, 17 were done without confirmation by

iodized poppy seed oil. In only 1 case was the lesion not found. Iodized oil was used in 9 cases. The iodized oil films were positive in 6 of these and disks were found. They were negative in 2 cases in which herniated disks were found to be absent. The iodized oil was considered negative in 1 case in which a small disk was found.

Part II is devoted to the diagnosis and management of reflex sciatic pain.

PART I. ROOT COMPRESSION WITH
RADIATING PAIN

Although herniated intervertebral disks were witnessed by Virchow and cases have been sporadically reported since his time,¹ and although Goldthwait described their pathology in 1911,² it was not until 1934 that Mixter and Barr³ correlated the pathology with the sciatic syndrome as we know it today. Interest was excited and as is true for any syndrome of definite

Fig. 1—An example of a complete filling defect in the iodized oil column due to a herniated disk between the fourth and fifth lumbar vertebrae. The herniation was large and extended all the way across the spinal canal. Note however that iodized oil passed by the lesion freely and was not completely blocked as might be the case with tumor. When the patient is lying on his back the defect (D) appears complete. This type occurred three times in 46 cases.

understandable cause, it required only a few years to become established and its various aspects generally agreed on by the profession. We are reporting the results of our experience with 63 laminectomies with reference chiefly to a method of differential diagnosis and to the interpretation of the iodized oil column.

ANALYSIS OF CASES

Sixty-three laminectomies were done, with iodized oil studies in all cases. Herniated disks were found in 50 cases.

Proved Herniated Disks (50 cases) —There were 38 males and 12 females

The incidence of cases by decades was first 0, second, 3, third, 7, fourth, 13, fifth, 16, sixth, 10, seventh, 1, eighth, 0

Segmental Location —The disk was below the fourth or fifth lumbar vertebra in 46 cases (92 per cent) It was below the seventh cervical in 1 case below the ninth dorsal in 1 case and below the third lumbar in 2 cases

The patient with the cervical disk complained of pain in the ulnar distribution of the right upper extremity. An iodized oil study proved the presence of the herniated disk.

The patient with a disk at the ninth dorsal vertebra presented a tumor syndrome (transverse myelitis at the ninth dorsal vertebra)

One patient with a disk at the third lumbar vertebra complained of pain radiating to the left knee and related the onset to a back injury. The knee jerk on the same side as the laterally placed disk was absent. The other patient with a disk at the third lumbar complained of pain radiating to the foot only on the right. His legs and ankles were decidedly weakened and both knee jerks and ankle jerks lost. The herniated disk was large, ruptured and extended completely across the spinal canal.

Analysis of Disks at the Fourth or Fifth Lumbar (46 cases) —History. The onset of low back pain was sudden and related to a definite injury in 36 cases (78 per cent), there was no relation to injury in 7 cases (15 per cent) and the history was questionable in 3 cases (7 per cent). The shortest period given

Fig 2—Definite unilateral defect due to a herniated disk below the fourth lumbar vertebra on the right. Such defects usually have a ragged outline. Note that the defect involves the position of the axillary pouch of the fifth lumbar nerve on the right. This type of defect occurred in 18 cases out of 46. One of these cases presented the defect at the fourth and fifth lumbar vertebrae as the result of a herniated disk at each location. A, typical axillary pouches below the third lumbar vertebra. R, arachnoid root sleeves containing iodized oil. D, defect due to the herniated disk.

Of the 36 cases with a history of injury the onset of pain radiating down a lower extremity occurred sometime after the low back pain in 27 cases (75 per cent) and was given as concomitant with the back injury in 9 cases (25 per cent).

Of the 27 cases the shortest period between the onset of radiating pain and low back pain was two days, the

Fig 3—Mild defect due to a herniated disk between the fifth lumbar and the first sacral vertebra on the right. The apparent bilateral defect at F is not due to a disk. All iodized oil contained within the outer arrows at F is within the dural canal. The oil streaming down at the lateral aspects of this region is enveloping the intradural roots destined to emerge at A₅ (the fifth lumbar roots). The filling defect caused by the roots can be seen (R). The axillary pouches below the fourth lumbar vertebra and designated as A₄ are intact. The fusiform column of iodized oil between the inner arrows at F is sometimes all that is seen between two pairs of axillary pouches. Such a constriction has no pathologic meaning and a study of this film clearly shows how it is formed. See figure 7 under false defects. The true defect is a mild notch at D which obliterates the axillary pouch between the fifth lumbar and first sacral vertebrae on the right. S₁ is the corresponding pouch on the left. Six instances of this mild type of defect occurred among 46 cases. One case showed the defect at the fourth and fifth lumbar vertebrae.

longest period, fifteen years. The usual period varied greatly from weeks to years.

All 46 patients described radiating pain down the posterior aspect of the thigh and at least to and involving the leg—usually the lateral aspect or calf of the leg. Thirteen of these patients said there was no pain in the foot. Thirty-three (72 per cent) described pain radiating to the foot—usually the ankle dorsum or ball of the foot. In these two groups (radiation to leg or to foot) no definite correlation could be made between the type of radiation described and the fact that the disk was below the fourth or fifth lumbar vertebra. There was about an equal distribution of the two locations in each group. Hence we feel that a specific localization of the disk at the fourth or fifth lumbar based on the patient's localization of the radiating pain is faulty and should not be entirely depended on at the time of operation.

Some form of paresthesia was definitely described in 39 cases (85 per cent). Paresthesia strongly indicates organic involvement of the nerve root in question as opposed to reflex pain and is a dependable symptom. There was apparently no paresthesia experienced in 7 cases (15 per cent).

between the onset of low back pain and removal of the herniated disk was two months, the longest twenty-five years. The usual was two or three years.

3 The segment of iodized oil column between two pairs of axillary pouches may present a waistlike or fusiform constriction of varying degree. This is shown particularly well in figure 7. We feel that even though this constriction is pronounced it has no pathologic significance. It is probably occasioned by the fact that the oil does not fill out the subarachnoid space laterally, owing to the presence of the nerve roots which are destined to emerge from the next lower exits from the cul-de-sac. This is brought out especially well in the analysis of figure 3.

In respect to the iodized oil studies of the low lumbar region the cases fall into the following groups:

- A Positive iodized oil and herniated disk found, 46 cases
- B Positive iodized oil, the herniated disk is thought to have been missed, a group of 5 earlier cases
- C Negative iodized oil, herniated disk found, 1 case
- D Negative iodized oil, no herniated disk found, 3 cases
- E False iodized oil defects, no herniated disk found 5 cases

GROUP A—*Iodized Oil Positive and Herniated Disk Found* (46 cases)—In analyzing the iodized oil films we have classed the defects according to the following types: 1 Complete, in which a filling defect extends completely across the iodized oil column. 2 Definite unilateral defect, in which a definite notch is cut out of the iodized oil column on one side. 3 Definite bilateral defect, in which a definite notch is cut out of the iodized oil column on both sides at the same segment. 4 Mild defect, in which there is a mild filling defect at an axillary pouch. 5 Root sign, in which there is no filling defect in the iodized oil column proper but there is some displacement of the root from its normal course or a blunt cessation of the passage of iodized oil down the root sheath. The latter interpretation is aided by the visualization of a normal root opposite to the defective one.

The incidence of these types of defects in the 46 cases of disks at the fourth and fifth lumbar vertebrae is as follows:

- 1 Complete defect, 3 cases
- 2 Definite unilateral defect 18 cases (1 case showed this defect at the fourth and fifth lumbar vertebrae)
- 3 Definite bilateral defect, 6 cases (2 cases each showed two bilateral defects)
- 4 Mild defect 6 cases (in 1 case this defect was present at the fourth and fifth lumbar vertebrae)
- 5 Root sign, 13 cases

Diagnoses were made from all of the aforementioned defects previous to operation and found to be correct at operation.

Instances of each type of defect are given in the illustrations as follows:

- Complete defect, figure 1
- Definite unilateral defect, figure 2
- Mild defect, figure 3
- Root sign, figures 4, 5 and 6

GROUP B—*Positive Iodized Oil, Herniated Disk Thought to Have Been Missed*—There were 5 cases in this group. They were earlier cases and we were not so keenly aware of the necessity of exploring far laterally in the spinal canal. At this time we were using the transdural approach in some cases and obviously might overlook a small laterally placed herniation. When no disk was found, an appropriate sensory root

was cut or intervertebral canals were unroofed. The results were good and all 5 patients were relieved of pain. On reexamining the iodized oil films we are convinced that herniated disks are present in these cases. Unilateral definite defects were present in all cases.

When operating on small or medium lateral disks we have often had the feeling that the decompression alone, effected by removal of a laminal arch and ligamentum flavum, would be followed by relaxation of the involved root and relief of pain, although the underlying disk herniation still remains.

GROUP C—*Negative Iodized Oil, Herniated Disk Found* (1 case)—There has been only 1 case in which we felt that the iodized oil roentgenogram was entirely negative and yet at exploration a herniated disk (small and laterally placed below the fifth lumbar vertebra) was found. The clinical history and examination were sufficiently typical to warrant exploration. Even in this case when the facts were known, we felt that a root sign was demonstrable on reexamining the films. We feel that it is significant that only 1 case falls in this group, because it attests the reliability of the iodized oil study. It is equally significant that 8 cases (3 in group D and 5 in group E) were classed as negative iodized oil and false iodized oil defects respectively and, when exploration was done, no herniated disk was found.

GROUP D—*Negative Iodized Oil, No Herniated Disk Found* (3 cases)—These 3 cases showed clinical syndromes that warranted exploration in spite of a negative iodized oil study. Herniated disks were carefully searched for but none were found. Appropriate sensory roots were sectioned, based on the distribution of pain and the results were good.

When the sensory portion of the fifth lumbar or first sacral root is cut, the patients are conscious of numbness in the distribution of the cut root. They appear to become accustomed to it however and much prefer it to the former pain. In fact the same type of numbness at times follows the removal of a herniated disk and is probably due to a little too vigorous retraction of the dural sheath of the root while removing the pathologic tissue. The subjective numbness in this instance is greater than the demonstrable hypesthesia but is not cause for great complaint.

It has often been stated that involvement of a single sensory root is not sufficient to cause a demonstrable hypesthesia. Recently, however, we have been encouraged to find that, if we test comparable loci on the legs and feet with equal stimuli of light touch and pin prick so that the patient may compare the normal with the pathologic side, a definite hypesthesia can be demonstrated. This is true in the event of a single herniated disk below the fourth or fifth lumbar vertebra and appears to be more consistent on the lateral aspect of the calf or the lateral aspect of the ankle or medial side of the foot.

GROUP E—*False Iodized Oil Defects, No Herniated Disk Found* (5 cases)—Five patients were submitted to exploration for herniated disks because the history and examination, though equivocal in some ways, warranted an investigation. No evidence of herniated disk was found. Two of the iodized oil roentgenograms are analyzed in figures 7 and 8. We have classified the filling defects as false or artefacts and we feel that their

character serves to strengthen the dicta which we have proposed concerning the significant defects

It will be noted that all the patients in this group as well as those in Group D were relieved of pain following exploration. In these cases when a herniated disk was not disclosed either the intervertebral canals were par-

Fig 7—False defect. A good example of a constriction between two pairs of axillary pouches without pathologic significance. *A₄* and *A₅* region of axillary pouches at the fourth and the fifth lumbar vertebra respectively. *F* false defect the formation of which is clarified by an analysis of figure 3

tially opened or a sensory root sectioned in a location that was thought to be in keeping with the distribution of the pain.¹¹ This relief of symptoms was not only fortunate for the patients but raises some interesting speculations. In group D and also in this group of false iodized oil defects, except for the patient who proved to have an aneurysmal varix of the cord one might deduce that causes other than herniated disk may occasionally be responsible for root pain at the fourth and fifth lumbar vertebrae and the question of constriction of the nerve in the intervertebral canal following injury to the spine again intrudes itself. Two of these patients presented an absent ankle jerk. It may be recalled in this connection that a traumatic neuralgia of an intercostal nerve following an injury of the dorsal spine occasionally occurs. At any rate when a patient gives a fair or good history for herniated disk and exploration proves negative the question of management becomes acute. We feel that a partial unroofing of the intervertebral canal of the root or roots in question is indicated. The results have been as favorable as when a herniated disk is found and removed.

A brief account of the cases in this group is given. We feel that this type of case will be encountered from time to time and deserves further consideration because it constitutes a more puzzling problem than a straight forward herniated disk.

The speculations aroused concerning the relief of symptoms in those earlier patients who presented posi-

tive iodized oil findings and in whom we believe we failed to expose the pathologic condition are considered in the section devoted to that group (B).

CASE 1—E M, a man aged 65, had sciatic pain on the right side for three months. There were no history of injury and no back pain. The pain radiated to the right calf and lateral aspect of the foot. The calf was 15 cm smaller than that on the left. The ankle jerk was lost on the right side.

The column of iodized oil showed symmetrical hour glass constrictions between the axillary pouches of the third and fourth and between the fourth and fifth lumbar vertebrae. There was no defect at the location of any axillary pouch.

The regions of the fourth and fifth lumbar and first sacral roots were carefully inspected and no evidence of a pathologic condition of the disks was found. The ligamenta flava appeared normal. The fourth and fifth intervertebral canals on the right were partially decompressed. The result was good and the patient was relieved of his pain.

CASE 2—W A, a man aged 56, had pain in the back for eight years following a back injury. Sciatic radiation involved the leg and the foot in the left first sacral distribution. There was paresthesia and an absent ankle jerk on the left. The laminal arches of the fourth and fifth lumbar vertebrae were removed and careful inspection of the usual regions revealed no evidence of a herniated disk. The sensory portion of the left first sacral root was sectioned. A good result was obtained and the patient was relieved of his pain.

The iodized oil roentgenogram is shown in figure 7.

CASE 3—W S, aged 51, experienced gradual loss of strength in the lower extremities for four months accompanied by pain and numbness in both feet and legs and pain along the sciatic course in both thighs. The spinal fluid protein was 130 mg per hundred cubic centimeters. An iodized oil study showed the defect seen in figure 8. A later study also showed a defect at the eleventh dorsal vertebra which was felt to

Fig 8—False defect. This artefact between the axillary pouches *A₃* and *A₄* on the left might easily be misinterpreted but its location contraindicates herniated disk and illustrates the importance of the axillary pouches as landmarks.

be a tumor. The canal from the second lumbar to the sacrum was examined and no evidence of herniated disk found. At the eleventh dorsal vertebra an aneurysmal varix was disclosed.

The iodized oil roentgenogram showing an artefact between the third and fourth lumbar roots on the left is shown in figure 8.

11 We have now for some time abandoned the practice of cutting sensory roots because decompression of only appropriate roots in these cases has been followed by good results.

CASE 4—D J, aged 42, had low back pain for a year and a half following a back injury. There was sciatic radiation on the left side involving the leg, ankle and foot. There was no exaggeration of pain on coughing and sneezing and no diminution of ankle jerk but there was a mild hypesthesia over the entire left leg.

The column of iodized oil showed a large unilateral defect between the axillary pouches of the second and third and an hour glass constriction between the pouches of the third and fourth lumbar vertebrae. There was no defect at any axillary pouch.

The usual regions were carefully examined from the second lumbar to the first sacral vertebrae and no pathologic condition of the disks was found. There were some unusually large extradural veins on the left from the second to the fifth lumbar vertebrae which, judging from their proximity to the emerging roots, may possibly have had some significance. The intervertebral canals on the left side were partially decompressed. The result was nevertheless good and the patient was relieved of pain.

CASE 5—B J, aged 55, had pain in the right hip radiating to the right knee and ankle of five and a half months' duration. The pain was accentuated by heavy lifting but not on coughing or sneezing. The ankle jerk was not lost. On the whole the history and examination were equivocal for herniated disk.

The column of iodized oil showed what appeared to be a definite unilateral defect on the right and above the axillary pouch below the fourth lumbar. The pouch was not directly involved. Applying what we had learned about iodized oil indications, it was our feeling that the defect was an artefact. The laminae arches of the third, fourth and fifth lumbar vertebrae were removed and the usual regions carefully inspected without disclosing any pathologic condition of the disks. The intervertebral canals on the right side were partially decompressed. The result was good and the patient was relieved of pain.

COMMENT

Etiology—Trauma to the spine undoubtedly plays an important role. The trauma usually manifests itself as a sudden severe pain or "catch" in the lower part of the back at a time when the patient is lifting a weight less often from a twist or fall. The mechanism is one in which a great compressive force is exerted on the intervertebral disks by compression and flexion of the spine. The mechanism is probably responsible for the overwhelming incidence of the pathologic condition at the disks below the fourth and fifth lumbar vertebrae. The leverage is greatest at these points and the articulating planes of the facets are in the sagittal plane. Spurling and Bradford¹² report that 90 per cent of the herniated disks in their series occurred below the fourth or fifth lumbar vertebrae. Spurling and Grantham¹³ later reported 99 per cent. Robinson¹⁰ reported 95 per cent of 75 cases. The incidence at the fourth or fifth lumbar vertebra comprised 92 per cent of our 50 cases.

We feel that the initial event in the development of a herniated disk is a severe compression of the nucleus pulposus between the cartilaginous disk plates. This may occur with or without a rotary shearing of the articular facets. If the latter injury occurs, the patient is struck with a severe pain in the lower part of the back that may occasion his stay in bed for a few days or weeks. In any case the injury to the nucleus pulposus causes a loss of its integrity followed by sequestration and desiccation. The resulting material under ordinary stresses and strains is subject to gradual herniation through the annulus fibrosus and through

the weakest place in the posterior longitudinal spinal ligaments, which is at their lateral margins. Hence we feel that the herniated disk with its attending root signs and symptoms is a by-product of a back injury and requires time to develop after the injury. Most of our patients have clearly differentiated between the injury associated with low back pain and the subsequent development of radiating root pain. Even in the minority of patients who describe the root pain as being coincident with the back injury we are inclined to feel that there has been a preceding back injury. Indeed, some patients describe repeated "catches" in the back while lifting and which ultimately come to be associated with pain radiating to the leg and foot. The repeated strains serve to enhance the herniation of an already disintegrated nucleus pulposus. Mixer and Barr¹⁴ reported that back pain preceded the leg pain in 48 per cent of 123 cases.

Ultimately the nuclear material may actually rupture the posterior longitudinal spinal ligament in the line of its fibers and extrude itself into the spinal canal. So completely has the nucleus become sequestered in some cases that one of us (O H) by grasping the exposed portion with forceps has been able to extricate the mass in toto from its bed between the cartilage plates, leaving a cavity lined by smooth glistening walls.¹⁵ There appears to be some confusion in the use of the terms herniation and rupture. We choose to refer to any pathologic protrusion of the disk as a herniated disk. It may be ruptured or unruptured depending on whether or not it has in part or entirely extruded itself through the posterior longitudinal spinal ligament.

A history of back injury is given by various authors as occurring in the following percentage of cases: Mixer¹⁶ 60 per cent, Love¹⁷ 58 per cent of 500 cases, Mixer and Barr¹⁴ 49 per cent of 123 cases and in our series 78 per cent of our cases.

Ligamentum Flavum—We have not encountered a case in which we felt that a hypertrophied ligamentum flavum was an entity or responsible in itself for root pain. It is an unyielding bulwark against which the herniated disk pinches an emerging root, and after carefully dissecting and studying the ligament in a number of cases we are not convinced that it plays any other pathologic role. Even if it should be hypertrophied, in the absence of a herniated disk we do not believe that it could be responsible for root pain.

Horwitz¹⁸ in an anatomic study of 75 human cadavers found no instance in which the ligamentum flavum exerted undue pressure on the caudal nerve roots. Apparent forward bulging of the ligament which constricted the intervertebral foramen was found between the fifth lumbar and the first sacral vertebra in 4 specimens and between the fourth and fifth lumbar vertebrae in 2 specimens. The bulge was found to be due to advanced proliferation of the articular facets of the apophyseal joints and not to be hypertrophy of the overlying ligamentum flavum. Love says "The important point to remember about the ligamentum flavum is that although it may be of sufficient size to compress

the nerve roots, causing intractable pain, this phenomenon without an associated protrusion of the disk is rare."

Clinical Symptoms and Signs—The typical unequivocal case may be described as follows. The patient tells of an injury to his back some months or years before. The suddenly acquired low back pain may have been severe enough to require a few days in bed and has never completely subsided. There may have been subsequent sharp pains in the lower part of the back associated with heavy lifting but in any case some time later he experiences a new type of pain which he describes as radiating down the back of the thigh and then to the calf and some part of the foot or ankle. The pain is toothache-like in character and may be augmented by sharp jabs when certain positions are assumed. Paresthesias are experienced in the leg or foot in the form of numbness or "pins and needles." Coughing and sneezing exaggerate the pain.

The patient walks with a stiffened back, obviously uncomfortable and with a slight list usually toward the painful side. The list may be away from the painful side. He sits down slowly on the opposite buttock favoring the painful leg. On examination movements of the back are limited in all directions and the erector spinae muscles are spastic, particularly on the painful side. The straight leg raising test is positive, especially on the same side and accompanied by pain. The region of the sciatic nerve and the calf muscles are tender. Motor strength of the lower extremities is usually unimpaired. Sensation is unimpaired but a mild hypesthesia to light touch may be discerned over the lateral aspect of the leg or at some place on the foot or ankle. The knee reflexes are equal, but the achilles tendon reflex on the painful side is absent or diminished. Under such circumstances one can make a diagnosis of herniated disk below the fourth or fifth lumbar vertebra. Good clinical descriptions of herniated disk are given by Macey,¹⁰ by Spurling and Grantham¹³ and by Mixer.¹⁶ The last mentioned gives an account of the earlier literature.

Many cases will not be typical, however, but will present only some of the elements of the syndrome. The syndrome may be considered as that resulting usually from a compression of the motor and sensory fibers of a single nerve root. The severity of the pain and motor signs depends on the severity of the compression. Of all the symptoms and signs we feel that the location and character of the radiating pain, particularly when accompanied by paresthesia, is the most important and should lead to the diagnosis of small laterally placed disk herniations.

Spurling and Grantham¹³ and Spurling and Bradford¹² feel that the ankle jerk is uninvolved if the disk is below the fourth lumbar and that it is diminished or absent if the disk is below the fifth lumbar vertebra. Our experience does not agree with this statement (as shown in the analysis of cases). We feel that the ankle jerk may or may not be involved in the event that a disk is at either the fourth or the fifth lumbar vertebra and that involvement depends on how severely the motor root is compressed. Pain undoubtedly precedes any involvement of the ankle jerk.

Although the radiating pain involved the leg or foot in all our cases, Mixer and Barr¹⁴ report pain in the thigh in only 13 per cent of their cases. It involved the calf in 66 per cent and the foot in 21 per cent.

Lumbar Puncture—A herniated disk at the fourth or the fifth lumbar vertebra will be caudal to the usual lumbar puncture and hence even if it should be a large herniation it would not impair the measurable dynamics of the spinal fluid. Even though the protein content of the fluid is higher than 45 mg per hundred cubic centimeters in 17 per cent of our cases we do not feel that this fact has been particularly helpful. In a series of protein determinations on what we believe to be normal spinal fluids the fluctuation in values was very similar to that in our disk cases. Barr, Hampton and Mixer⁹ state that increased protein may result from irritation of nerve roots without necessarily having a block. Hence an examination of the first fraction of fluid withdrawn may show more protein than the second fraction.

THE OPERATION

Cases have been reported by Love²⁰ and by Hamby²¹ in which the disk herniation was removed without removal of any bone. Removal of the ligamentum flavum provided sufficient exposure. At most in many cases they make only a partial removal of the lateral half of a laminal arch. Such minimal exposures are commendable and at times have proved satisfactory in our hands also. We prefer, however, to chip away a portion of an entire laminal arch. If the disk is between the fifth lumbar and the first sacral the lower margin of the laminal arch of the fifth lumbar vertebra is chipped away and the ligamentum flavum on both sides removed widely. If the disk is between the fourth and fifth lumbar vertebrae the lower margin of the fourth and the upper margin of the fifth are rongeuired away. In our experience the herniation usually lies in part under a laminal arch, and in some cases it has rested entirely under it so that it was not exposed until the arch was entirely removed. This has been especially true of herniated disks that have rested under the laminal arch of the fifth lumbar vertebra. Recently in searching for a disk we rongeuired away the lower third of the fifth arch and then its upper third leaving only the middle third as a rim. Finally and not until this was removed could a small laterally placed disk be disclosed. Furthermore the apparently thorough decompression which had been made would not have been effective in relieving the involved fifth lumbar root had the further exploration not been made. Although the relation of the herniated disk to a nerve root is constant its relation to the laminal arches is not always exactly the same. The total removal of the fourth and fifth lumbar laminal arches has in no way incapacitated our patients if the articular facets have been left intact. We would sound a note of caution against too great stress on minimal exposures, particularly when the exploration is made on the basis of clinical findings only and without the aid of visualization with iodized oil. While we begin the operation with a minimal exposure we do not hesitate to enlarge it in the interest of a thorough exploration even to the removal of three laminal arches if warranted by the history and clinical findings.

Often the herniated portion of the disk is quite laterally situated and unless the exploration is carried far laterally clear to the intervertebral canal such a lesion may be overlooked. Palpation of these locations with the index finger will ordinarily betray small herniations but if one is in doubt it is well to retract the

19 Macey Harry B Clinical Aspects of Protruded Intervertebral Disk Arch Surg 40 433-443 (March) 1940

root in question and explore the disk up to the point where the nerve enters the intervertebral canal. After the ligamentum flavum between the fifth lumbar and the first sacral arches has been thoroughly removed one can usually palpate a hump with the finger tip just under the first sacral arch. This is a normal configuration of the body of the first sacral vertebra and should arouse no concern.

While there will be the occasional case in which the lesion is best exposed between a root and the dural cul-de-sac, the most effective maneuver is retraction of the nerve root mesially. There are three reasons for this. The maneuver usually provides greater exposure of the herniated disk, small disks are often quite laterally situated and there is often a rich plexus of veins in the "axilla" which the root makes with the cul-de-sac and which gives troublesome bleeding when disturbed.

If the posterior longitudinal ligament is not already ruptured it is incised or the dome of the protrusion uncapped and all available sequestered disk material curetted away. When a herniated disk is found on one side, the ligamentum flavum on the opposite side is removed and that side carefully explored also. Such an exploration has in some cases revealed an early herniation which, though symptomless at the time, may well have produced symptoms later on.

If iodized oil has been injected, a small incision is made in the dura at the conclusion of the operation and the oil is allowed to escape, being aided by elevating the head of the operating table upward.

The average patient is kept in bed two weeks and then allowed up as tolerated. He is cautioned not to lift heavy objects or strain his back for two months.

We have not felt that spinal fusions are indicated after removal of an uncomplicated herniated disk, but in view of our premise of initial back injury we should not become oblivious to its consideration. At present an evaluation of the role played by a back sprain and that played by a herniated disk in the causation of low back pain is difficult. Perhaps more follow-up studies will be helpful. In any case it is probably well to solicit the judgment of the orthopedist in this particular matter.

RESULTS

The results following extradural removal of herniated disk have been excellent. The patient usually realizes that he is free from what was a very agonizing and incapacitating pain as soon as he recovers from the anesthetic. The relief of this type of root pain is in many ways comparable to and as spectacular as the relief of the pain of tic douloureux following a partial section of the sensory root of the fifth cranial nerve and marks a decided advance and achievement in the neurologic surgery of pain syndromes.

One patient in our series extending over a period of three years returned complaining of a recrudescence of his former pain. A herniated disk below the fifth lumbar vertebra on the right side had been removed three months previously. Reexploration revealed that the region from which the pathologic material had been removed was in excellent order. There was no recurrence of the herniation. The intervertebral canal at that location was then partially unroofed. The patient has again been free from pain to the time of writing (three months).²² It was interesting to find that healing of the wound was exceptionally good and the scar tissue formation over the spinal canal very dense. The

scar tissue was not especially adherent to the dura, however, and the plane of cleavage could be easily effected.

PART II THE REFLECTED SCIATIC PAIN, THE DIFFERENTIAL DIAGNOSIS BY THE PROCAINE TEST

The phenomenon of referred sciatic pain is most strikingly represented in the clinical syndrome of the herniated intervertebral disk. In our series the percentage of correct diagnosis of this condition, as proved by biopsy, was high (90 per cent), but this high average can be attained only by insisting strictly on certain diagnostic prerequisites over and above the radiating sciatic pain, these are the traumatic pathogenesis, the neurologic signs and the visualization of the disk by x-ray examination. In other words, the diagnosis must be positive and confirmed by the presence of pertinent symptoms rather than by exclusion.

Sciatic pain due to pressure of the disk on the sensory spinal root is of mechanistic origin. So also is sciatic pain from certain other causes for instance in arthritis or in congenital anomalies of the spine, in which it results from narrowing of the intervertebral foramina and encroachment on the spinal nerves. There is, however, this difference between the two situations. We have little or no anatomic proof of the compression of nerve roots by the intervertebral foramina in arthritis, except in solitary instances in which the anatomic distribution motor and sensory, of a single nerve root absolutely identifies the condition, whereas in the case of the protruded disk not only is there a definitely established anatomic entity but the relief which follows the removal of the disk proves that it actually is the pain producing agent.

Thus the student is in the fortunate position to develop a very definite clinical pathologic picture based on authenticated cases. We notice particularly that the sciatic radiation is by no means all that is necessary to make the diagnosis of a ruptured disk, the mode of onset, the distribution of any paralysis, the type of pain and the presence of concrete disturbances (paresthesias, reflexes, touch and so on), indicating compression of a peripheral nerve, and finally the visualization of the disk in the roentgenogram, are all essential diagnostic features.

It is this careful reservation that the diagnosis of compression or referred pain must be contingent on more concrete evidence than mere radiation which has opened the way for a real discrimination in interpreting sciatica. For one thing it has done away with the one time cherished mechanistic concept that all sciatica is the result of mechanical pressure and that there is no other possibility of its origin.

There is, indeed, another possible source of the pain phenomenon, namely that it is of reflex origin. By this is meant that the pain impulse travels from a peripheral point, in this case the strained soft structures of the back, centripetally to the spinal cord, and makes then synaptic contact with other sensory units at different levels and with different anatomic distribution, with the result that pain sensation is recorded in the territory of the second unit.

If such a type of reflected sciatic pain is found to exist, it must be carefully differentiated from that kind of referred sciatic pain which is due to direct pressure acting on the posterior roots or on any other point of the peripheral nerve.

²² See discussion under Group E False Iodized Oil Defects

The reflex character of such a sciatic pain can be proved only if the reflex arc can be interrupted at the point of the primary local irritation, in this case the soft tissue lesion in the back, and if such an interruption immediately and absolutely abolishes the radiation along the sciatic nerve.

In the case of the low back pain this is facilitated by the fact that many patients show so-called trigger points, that is, small, strictly localized and distinctive areas of pain on pressure (fig 9). These are most frequently the lumbosacral junction, the posterior superior iliac spine, the gluteal insertion at the outer posterior rim of the ilium and the posterior border of the tensor fasciae.

Anatomy teaches us that all these structures as well as all ligamentous, tendinous and aponeurotic structures of the lower part of the back receive their sensory innervation from the posterior primary division of the lower lumbar and of the sacral nerves. The sciatic trunk, on the other hand, composed of the last two lumbar and first three sacral roots, is entirely constituted by the anterior primary divisions of the spinal nerves. There is no communication between the two territories of the anterior and the posterior primary division, and any synaptic connection between these two systems must occur not lower than in the spinal ganglions or, more likely, in the spinal cord itself through the lateral horns and the spinothalamic pain conducting tract.

For the past five years we have been able to prove that some sciatic radiations associated with low back pain are of this purely reflex character. This proof is furnished by producing or intensifying sciatic radiation by simple stimulation of the circumscribed painful area in the back and, furthermore, by the fact that infiltration with 5 to 10 cc of a 1 per cent solution of procaine hydrochloride into this area at once abolishes the sciatic radiation. It thus has become established that among cases of sciatic radiation there are some which have nothing to do with mechanical irritation of the posterior roots but are caused by local pain centers at the back, which excite by reflex routes other pain centers in the cord, situated at different levels, and the stimulation of which is recorded as sciatic neuralgia.

Clinically there is a difference between this type of neuralgic sciatic pain and the radiation due to direct posterior root irritation such as exists in herniated disks. First and foremost of all, the reflex sciatic pain is purely neuralgic and there are no signs of disturbances of other sensory qualities: no paresthesias, anesthesias or changes in the deep reflexes.

Second, the radiating pain follows the local back pain, often only after later attack, as a sort of cumulative effect of afferent pain impulses, and, third, there is no strict anatomic distribution of the radiation such as is seen in herniated disk and the pain does not reach into the sole or heel of the foot.

In none of the cases of purely reflex sciatica, so proved by a positive procaine test, was there paresthesia, anesthesia, loss of reflexes or anatomic extension of radiation to the outer side of foot or heel.

HOW THE PROCAINE TEST IS TO BE CARRIED OUT AND HOW IT IS TO BE INTERPRETED

The test is to prove the connection between local back pain radiation. Hence no patient is eligible for it unless there is a distinct trigger point present and he does show definite radiation. We use 1 per cent solution of procaine hydrochloride without epinephrine and inquire of the patient if he has any idiosyncrasy to procaine.

Since most of them have had teeth extracted at some time or other, they are able to give this information.

While the patient is on the table in the prone position, the trigger point is marked with mercuric iodine and the field is swabbed with half strength iodine benzene solution. The skin is anesthetized with a few drops of procaine hydrochloride solution and a long lumbar puncture needle is then inserted through the soft tissues to the periosteum. The fascia and sheath are then poked through in several places until the patient volunteers the information that he feels not only pain at the trigger point at the back but also a definite radiation down his leg.

After injection of 6 to 10 cc the trigger point must have disappeared and the patient states that the radiating pain down his leg likewise has vanished. The patient is then told to turn over and to lift the affected limb, knee extended. He is surprised to find that he can lift it without pain as well as he can the other limb. He is then told to get off the table and to walk. He now finds that he can walk with ease, can bend forward though he still may retain his lateral list.

Fig 9—Pressure points of lumbosacral syndromes: 1 Gluteus maximus syndrome 2 Sacrospinalis syndrome 3 Sacrolumbar syndrome 4 Transversosacral syndrome 5 Sacrococcygeal syndrome 6 Sacrotuberous syndrome 7 Tensor fasciae

We place a good deal of emphasis on avoiding any suggestions and on having the patient himself volunteer his expression of relief. Every possible chance of auto-suggestion should be eliminated and the patient should not know beforehand what relief to expect. The surprise element is a valuable sign of good faith. The patient is then told that he may expect the relief to last pending the action of procaine and no longer, and this may be a matter of hours or of days.

We are particularly anxious to see that the relief both local and of the radiation, is complete. There is no such thing as a partially positive procaine test. It is either strikingly positive or negative or noncommittal. We lay emphasis on the point that the patient is genuinely surprised, really taken aback, over the fact that he can raise his leg as high as the other, that back and sciatic pain have completely disappeared, that he bends over without trouble and that he can walk without discomfort.

The patient then is warned that with the wearing off of the procaine effect the pain, both local and radiating, will return. The free interval may last from several hours to several days. After this time the patients complain that the pain has returned "worse than ever." There is no reason for the returning pain being more intense than the original one. But the patient having enjoyed a brief spell of complete relief, keenly resents

the return of his complaint, against which he has to build up his tolerance a second time

As soon as the pain is under control by virtue of the procaine injection it seems best to start treatment without delay. Traction in bed in a direction corresponding to the position the patient assumes in standing (usually with the hip slightly flexed), together with hot packs and massage for the contracted back muscles, cathartics and acetylsalicylic acid is the standard treatment

The patient should remain in bed until the spontaneous sciatic pain has disappeared and until he is able to roll over in bed without any discomfort. He is then ready to be up, but on crutches only, and after he has been fitted with a proper support

In all cases of sacrolumbar strain and in cases of recurrent sacrospinalis strain we prefer the brace. A type which reaches just below the shoulder blades and has a pelvic and suprailiac cross band and a snug leather apron in front has served us best

In cases of complicating spinal arthritis a brace should be used which reaches higher up and is provided with shoulder straps

In cases of more acute sacrospinalis sprains, gluteal sprain and sprain of the fascia lata we prefer a corset supplied with a sacroiliac pad and reaching far enough downward to cover the gluteal region and the upper part of the thigh

In some cases in which hospitalization was impossible or inadvisable we have applied hip spicas reaching from the mamillary line over the affected side to the ankle, but no attempt is made to correct the asymmetrical position, either the forward flexion deformity or the lateral deviation. The cast is applied to the patient "as is"

Weight bearing on the affected leg is started very carefully and slowly, with the patient still on crutches, and the latter are discarded only when the patient himself is sure of the weight tolerance of the affected leg and then only for guardedly increased periods

We practice the treatment of the contracted muscle masses from the beginning. While the patient is in bed the muscles are relaxed by hot packs and light massage, while the patient is up on crutches vigorous massage and later graded exercises are instituted

REPORT OF CASES

(a) *Sacrospinalis Syndrome*—CASE 1—P H, aged 17 years, had pain and stiffness of the back with radiation to the right thigh following occupational strain of two months' duration and sciatic scoliosis. A trigger point was present in the right posterior superior spine. Reflexes were normal. Kernig's sign was present. Procaine into the trigger point gave a positive test. Conservative treatment (as described), traction, corset and physical therapy, was employed. Complete relief was obtained. Observation has been continued for three years

CASE 2—L McC, aged 58, had low back pain with sciatic radiation on the left side to the foot for seven months. A trigger point was present in the left posterior superior spine. Kernig's sign was present. Reflexes were normal. Procaine into the trigger point gave a positive test. Conservative treatment (traction, support and physical therapy) effected complete relief. The patient has been under observation for two and one-half years

CASE 3—E B, aged 49, had low back pain with right sciatic radiation to the leg from strain. A trigger point was present in the right posterior superior spine. Kernig's sign was present on the right. Reflexes were normal. Procaine into the trigger point gave a positive test. Conservative treatment (corset and physical therapy) led to considerable improvement with only occasional pain. The patient has been under observation for two years and nine months

CASE 4—E M, aged 31, had low back pain with sciatic radiation on the left side to the leg for three months. A trigger point was present in the left posterior superior spine. Kernig's sign was present. Reflexes were normal. Procaine into the trigger point gave a positive test. Conservative treatment (corset and physical therapy) gave complete relief. The observation time has been one year

(b) *Lumbosacral Syndrome*—CASE 5—C R C, aged 25, had pain in the back and radiation in both thighs for eleven months following strain. A trigger point was present in the sacrolumbar junction. Kernig's sign was present. Reflexes were normal. Procaine into the trigger point gave a positive test. Conservative treatment (braces and physical therapy) gave complete relief. The observation time was one year and eight months

(c) *Combined Lumbosacral and Sacrospinalis Sprain*—CASE 6—J A K, aged 32, had low back pain and gluteal radiation with numerous recurrences for eleven years following a fall. A trigger point was present in the sacrolumbar region and right posterior superior spine. A bilateral Kernig's sign was present. Reflexes were normal. Procaine into the trigger point gave a positive test. Conservative treatment (corset and physical therapy) gave complete relief. Observation time was two years

(d) *Combined Sacrolumbar and Tensor Fasciae Strain*—CASE 7—B M, aged 33, had recurrent low back pain with left sciatic radiation to the ankle for five years following strain. A trigger point was present in the left posterior superior spine, tensor fasciae. Left Ober and Trendelenburg tests were positive. Reflexes were normal. Procaine into the trigger point gave positive tests with disappearance of the Ober and Kernig signs. Conservative treatment (corset and physical therapy) gave complete relief. Observation time was three years

(e) *Sacrobuterous Syndrome*—CASE 8—C J S, aged 49, had low back pain, bilateral sciatic radiation, following a fall, for eight months. A trigger point was present in the sacrobuterous ligament. Kernig and bilateral reflexes were normal. Procaine into the trigger point gave a positive test. Conservative treatment (corset and physical therapy) resulted in considerable improvement

(f) *Sacrospinalis Syndrome in Osteoarthritis*—CASE 9—M L A, aged 38, had recurrent low back pain with left sciatic radiation to the knee for seven years. A trigger point was present in the left posterior superior spine. Kernig's sign was present. Reflexes were normal. Procaine into the trigger point gave a positive test. Conservative treatment (brace and physical therapy) resulted in improvement. Observation time was thirteen months

(g) *Gluteal Syndrome*—CASE 10—E D, aged 45, had low back pain with left sciatic radiation to the calf for two years. A trigger point was present in the left gluteal region. Kernig's sign was present. Reflexes were normal. Procaine into the trigger point gave a positive test. Conservative treatment (corset and physical therapy) gave complete relief. Observation time was three months

CASE 11—M T, had low back pain with left sciatic radiation for one year following strain. A trigger point was present in the left gluteal region (posterior superior spine). Kernig's sign was present. Reflexes were normal. Procaine into the trigger point gave a positive test. Conservative treatment (traction, brace and physical therapy) gave complete relief. Observation time was four months

STATISTICAL REVIEW

One hundred and seventeen cases of low back pain with radiation and a positive procaine test were observed

End Results—Criterion. Continuous relief from immobilization by traction, casts, braces or operative fusion

Complete relief, 95 cases (85 per cent)

Partial relief, 18 cases (12 per cent)

No relief, 4 cases (3 per cent)

SUMMARY

1 Conditions of a positive procaine test are as follows

(a) The case must be suitable for the test by showing a definite trigger point at the back and sciatic radiation

(b) Insertion of the needle must increase the local pain as well as the radiation (voluntary information)

(c) Injection of procaine must abolish the local trigger point as well as the radiation and the Kernig sign must disappear (voluntary information)

(d) Precautions should be taken against any auto-suggestion by the patient

(e) The procaine test should not be accepted as proof unless it is strikingly positive

2 As to Treatment

(a) A positive procaine test promises the success of immobilization

(b) In most cases conservative immobilizing measures suffice (traction, plaster, brace, cast)

(c) In some cases operative fixation (fusion) is necessary

(d) In cases of strain of the fascia lata (positive Ober sign and tender point at fascia) the Ober operation is successful

(e) Physical therapy in the form of hot packs massage and graded exercises is an essential adjunct to the treatment

CONCLUSIONS

1 Low back pain accompanied by sciatic radiation may be due to

(a) Lumbosacral root compression A herniated intervertebral disk is the commonest causal factor The pain is referred and is ordinarily accompanied by other symptoms and signs of nerve root compression that are of diagnostic significance If a tender locus is present over the lower part of the back, sacrum or buttocks, local anesthetization of the locus will not abolish the symptoms or signs

(b) Myofascial trauma The radiating pain in this case is reflected and unaccompanied by symptoms and signs of spinal root compression If a tender locus (trigger point) over the lower part of the back, sacrum or buttocks is present, local anesthetization (procaine test) will abolish the pain temporarily and thus indicate the causal factor

Hence the procaine test is an additional valuable test in the differentiation of referred and reflex "sciatica"

2 Herniated intervertebral disk below the fourth or fifth lumbar vertebrae ordinarily invokes such a definite syndrome that myelography is seldom necessary to establish the diagnosis In the occasional equivocal case in which myelography is desired, iodized poppy seed oil is the medium of choice If 5 cc of the oil is used, the smallest, laterally placed hemiations will be indicated in the roentgenogram in a very high percentage of cases

3 In a small percentage of patients who present definite symptoms and signs of root compression, including an absent achilles tendon reflex, no herniated disk, concealed or otherwise, is found In this type of patient we advise complete removal of the fourth and fifth lumbar laminae arches and their accompanying ligamenta flava and partial unroofing of the intervertebral canals of the fifth lumbar and first sacral roots The results in this type of patient following such a decompression have been very encouraging

DECOMPRESSION OF PROTRUDED INTERVERTEBRAL DISKS

WITH A NOTE ON SPINAL EXPLORATION

ARTHUR ECKER M.D.

SYRACUSE, N. Y.

Exploration of the cauda equina in the region of the fifth lumbar vertebra for intractable low back and sciatic pain is now frequently performed by neurologic surgeons¹ For properly selected patients operation usually yields prompt and persistent relief from severe pain²

However, further refinement in technic is suggested by the appreciable percentage of patients who suffer persistent or recurrent minor discomfort in the back As emphasized previously,² exploration should be adequate and usually should include the anterior aspect of the spinal canal both above and below the fifth lumbar vertebra not only in the midline but also far laterally near the intervertebral foramen on each side At the same time the less laminar bone removed the more prompt will be convalescence and the less likely subsequent minor backache Furthermore while operation should be extensive enough to yield relief from pain, it should at the same time minimize the risk of recurrent symptoms In this paper I present two suggestions which have proved helpful, namely, the interlaminar approach to the spinal canal after bilateral stripping of the sacrospinalis muscle from the spinous processes and laminae and decompression of small intraspinal protrusions of intervertebral disks without removal of any of the disk structure

INTERLAMINAR EXTRADURAL EXPLORATION OF THE SPINAL CANAL AFTER BILATERAL STRIPPING OF THE SACROSPINALIS MUSCLES

Interlaminar exploration of the spinal canal was apparently first recorded by Love³ and by Hamby,⁴ who recommended unilateral stripping of the sacrospinalis muscle However, in most cases unilateral exposure of the spinous processes and laminae leads to certain technical difficulties In the first place there is considerable awkwardness in retracting the sacrospinalis group of muscles on just one side If a self-retaining laminectomy retractor of the Adson-Beckman type is used and the medial prongs are placed in the deep fascia, the retractor becomes rotated on its long axis and is awkward to manage, if the medial prongs are placed at the base of the spinous process the amount of exposure is appreciably diminished by the retractor itself If a retractor of the Hibbs type is used, the assistant's arm is in the way and there is a tendency for the patient to be pulled out of position on the operating table Because the exposure is so limited there is a considerable tendency for the surgeon to remove laminar structure in the region of the articular facets Naturally, if the facets are entered there is greater likelihood of instability of the vertebral structure at this level and, by the same token, greater risk of persistent backache Another important dis-

advantage of the unilateral approach to the spinal canal is the unilateral exposure of the spinal surface of the disk. Many neurosurgeons of experience have had patients with protruded intervertebral disks who have been relieved of sciatic pain on one side and who have had recurrence of symptoms on the opposite side.

Although I had been Dr. Love's first assistant when he did his first 6 cases of interlaminar approach to the spinal canal with the unilateral stripping of the muscles, in my own practice I had felt satisfied with this method in only 3 cases out of the first forty-five operations of this type which I performed. Furthermore, I had hesitated to strip the muscles on both sides because of the possibility of increasing postoperative discomfort. However, Bradford and Spurling⁵ have clearly recommended that "even when a strictly unilateral laminectomy is performed or when the removal of no bone is contemplated, it is advisable to strip the erector spinae muscles bilaterally in order that a self-retaining retractor can be placed to best advantage." As a matter of fact, the bilateral stripping of the muscles causes no more postoperative discomfort than unilateral stripping. Ordinarily after the muscles have been stripped on both sides it is advisable to remove the interspinous ligament and perhaps a minute amount of adjacent spinous process. This method permits finger exploration of the anterior portion of the spinal canal, at least at the lumbosacral level, in most cases. Naturally the laminae can be nibbled with rongeurs as far as seems indicated.

Since carrying out bilateral stripping of the muscles routinely in cases of suspected protrusion of the intervertebral disk, I have been able to perform adequate exploration of the spinal canal without removal of any portion of the lamina in 5 out of 9 successive cases. In the other cases of this series there was only minimal removal of bone, and in no instance of this group were the articular facets exposed or a neural arch interrupted. This method permits the use of a self-retaining retractor and of the ordinary overhead operating room light. It permits thorough study of the intraspinal structures and especially the relationship of the disk to the nerve roots and laminae.

The importance of not opening the dura in these cases can hardly be overemphasized. In the first place, leaving the dural sac intact provides a fluid buffer against trauma to the affected nerve root⁶ as well as to the rest of the roots of the cauda equina. In the second place, the pressure in the normally distended dural sac is invaluable in stopping bleeding from the epidural veins and may easily be supplemented by a small free muscle graft. Furthermore, it is highly desirable to avoid the introduction of blood in the subarachnoid space in avoiding not only immediate meningeal irritation but also the later development of adhesive arachnoiditis of the cauda equina. In addition, leaving the dura intact minimizes the risk of meningitis from an unsuspected tuberculous spondylitis or a possible postoperative infection of the wound. Finally the remote risk of postoperative development of extradural cyst (arachnoidal evagination) is obviated by leaving the dura intact. It may be asked whether midline protrusions of the intervertebral disks require transdural removal. It will be indicated later that midline protrusions of the disk rarely cause symptoms and in most

cases the disk structure should be left alone, especially if there is a bony ledge of vertebra above or below the protrusion. Naturally, the nerve roots should be adequately decompressed on each side.

When bilateral stripping of muscles and interlaminar exploration of the spinal canal are performed with or without removal of intraspinal protrusion of the intervertebral disk, patients have as little discomfort postoperatively as when the muscles are stripped from only one side. For example, they can turn themselves on a firm bed with little pain. Furthermore, if unable to empty the bladder when lying in bed, male patients may stand at the bedside, and female patients may sit on a bed pan twelve hours after operation. Convalescence is shorter than after laminectomy, and complaints of minor postoperative discomfort are appreciably fewer. A secondary operation could be performed fairly safely because the laminae are intact, and the periosteal elevator can slide along the bone with less danger of tearing the dura than if the bone has been removed.

DECOMPRESSION FOR SMALL OR MODERATE INTRASPINAL PROTRUSIONS OF INTERVERTEBRAL DISKS

When is a disk protruded? There is no question about massive protrusions of intervertebral disks which represent an intraspinal mass a centimeter or more in diameter. But these large tumors which are so gratifying to excise represent the minority of lesions disclosed at operation. Ordinarily the surgeon finds a disk which bulges more or less. Love⁷ judges whether the disk is protruded or not by its resilience or consistency as well as by the associated changes in the nerve root—edema, inflammation and possible adhesions. Since the intervertebral disk normally has a certain amount of intraspinal bulge, I consider a disk protruded only if it bulges more when the lumbar spine is extended as a result of the anesthetist's lifting the shoulders of the patient. This increase of protrusion on extension of the lumbar spine may seem paradoxical when compared with the fact that most protrusions begin when the lumbar spine is in flexion. However, the original protrusion is caused by a tear in the annulus fibrosus. The additional protrusion, when the lumbar spine is extended, is caused by a tendency of the posterior portions of the bodies of the vertebrae to act as pincers.

It is not the protrusion of the intervertebral disk itself which causes sciatic pain but rather the compression of the nerve root between the disk and the posterior wall of the intervertebral foramen. As Barr and Mixer⁸ state, "the lesion is laterally placed, usually directly beneath the articular facet." The problem, therefore, is to relieve the pressure from the nerve (or nerve root). In most cases pain produced by small and moderate protrusions of the intervertebral disk can be adequately relieved by removing the structure against which the nerve root is being displaced, namely the ligamentum flavum at its lateral extremity. Occasionally, in order to decompress the nerve root adequately it is advisable to remove some of the articular capsule to which the lateral portion of the ligament is attached,⁹ and adjacent portions of the laminae.

9 Naffziger H C Inman Verne and Saunders J B deC M Lesions of the Intervertebral Disk and Ligamenta Flava Surg Gynec & Obst 66 288-299 (Feb 15 no 21) 1938

The results in my complete series of 14 cases of definite protrusions in which this decompressive procedure has been carried out have been at least as favorable as in those cases in which the protruded portion of the intervertebral disk has been removed. In the immediate postoperative course there is less sciatic pain and tenderness because it has not been necessary to exert so much traction on the nerve root. When laminectomy is performed, I believe it best to require three weeks of postoperative hospitalization and three additional months before the patient returns to regular work. When an interlaminar excision is performed without removal of any portion of the intervertebral disk which may be more or less protruded, I have found just as good results by shortening each of these periods of time by one third. The late results in cases of protruded disk (which have been only decompressed) seem entirely satisfactory and there has been no recurrence of symptoms so far. One such patient underwent operation on Nov 20 1939 and has been working regularly as a truck mechanic without any discomfort ever since (twenty-nine months postoperatively at the latest report). The others have been followed for periods ranging from seventeen to two months. I hope that this method will minimize the incidence of recurrence of protruded intervertebral disk which is known to be at least 1 per cent⁶ and is likely to be higher with the further passage of time. In 1 additional case there was intraspinal protrusion of the intervertebral disks both above and below the fifth lumbar vertebra. I removed the larger protrusion but not the smaller. The postoperative result both in terms of relief from pain and in restitution to work was excellent at the time of the latest report twenty-six months after operation.

Leaving a stretched annulus fibrosus and posterior longitudinal ligament seems more reasonable than tearing through them completely and opening the way for additional fragments of intervertebral disk to protrude into the spinal canal later. After all, the major portion of the disk itself is undisturbed, no matter how large the fragment removed at operation. Naturally, large intraspinal protrusions or fragments which have torn loose from their attachments should be excised.

Furthermore, at operation for suspected protrusion there is found occasionally a perfectly normal disk which does not bulge into the spinal canal even when the lumbar spine is extended by elevation of the shoulders. It has been suggested¹⁰ that these "flat disks" are "concealed ruptured intervertebral disks." In some cases there is definite thickening of the ligamentum flavum. In others there may be compression of the nerve by dilatation of the veins¹¹ or by narrowing of the intervertebral foramen due to vertebral subluxation or proliferative bone changes.¹² In most such cases which are carefully selected and exploration done for protruded intervertebral disks and in which no protrusion is found there is relief following intra-

spinal exploration and decompression of the nerve root. There is no justification for excising a portion of intervertebral disk in any of these cases.

SUMMARY

The routine exploration of the spinal canal in the region of the fifth lumbar vertebra should be performed between the laminae after the erector spinae muscles have been retracted on both sides. This procedure has minimized postoperative discomfort and shortened the period of convalescence. Questionable slight and moderate protrusions of the intervertebral disk should be left alone and the overlying nerve root adequately decompressed. This procedure has yielded results as satisfactory as removal of the protruded portions of such disks and it may minimize the incidence of recurrence of symptoms.

TREATMENT OF IMPETIGO CONTAGIOSA WITH A NEW PHYSICAL FORM OF SULFATHIAZOLE

T. N. HARRIS, M.D.

PHILADELPHIA

The treatment of impetigo contagiosa presents a problem of considerable importance. The danger to the patient is by no means negligible, even after infancy and the great infectiousness and rapid spread of the lesions have always caused concern.

Until quite recently the therapy of impetigo was rarely considered in the medical literature. The two methods in general use were the application of solution of methylosaniline and that of ammoniated mercury several times a day, with removal of crusts as they formed. Since the outbreak of the present war, however, there has been a sharp increase in the frequency of such investigations, and many studies of new methods of treatment of impetigo have been reported in the British literature. This is quite in keeping with the natural history of the disease, since its spread is favored by a deterioration in sanitation and by crowding. The heightened importance of the problem of impetigo in the army, as well as in civilian life, is pointed out by Downie.¹

It is apparent also that the greater need for prompt healing and for checking the spread of impetigo in these years has evoked general dissatisfaction with older methods, since many of the recent papers deal with new ones. Moreover the number of forms of treatment suggested in these studies implies that an entirely satisfactory one has not been found. Within the years 1940 to 1942, more than ten different methods of treatment for impetigo have been offered and results of clinical investigation given in support of each one.

In addition to the sulfonamide studies, and concurrently with them, the following forms of therapy have been studied and suggested: copper sulfate-zinc sulfate lotion;² solution of ferric chloride;³ boric acid-zinc oint-

ment,⁴ hydroxyquinoline,⁵ staphylococcus toxoid,⁶ silver nitrate cautery¹ and mechanical occlusion by adhesive plaster. In addition to these, there have been reports by protagonists of the classic treatment by ammoniated mercury.

These studies report the percentage of cure ranging from 80 to 100 per cent, and the number of days required for the cure ranges from a few days to almost a month, usually ten to fourteen days. During this period treatments must be administered often and removal of crusts requires frequent attention.

The investigations of sulfonamide treatment have included several modes of administration. Studies have appeared on the use of peroral sulfonamides, sulfonamide ointments in various bases, and locally applied powdered sulfonamides. These investigations have yielded results which are more uniform than are those of the methods not employing the sulfonamides. A

The method devised by them yielded a stable suspension of fine crystals of sulfonamide. This suspension is presumably of natural crystals of the drug. It resembles magnesia magma in physical appearance and remains stable in pure water for at least many months. This last property presents an important contrast to the behavior of a crushed ordinary sulfonamide compound, which settles and cakes when suspended in water. Finally, when allowed to dry, the suspension becomes a fine, friable powder. These physical properties have extended the range of usefulness of the sulfonamides in local application. Studies of such uses have been reported.⁷

This new physical form of the sulfonamides has been named "microcrystalline" by Chambers, and a number of the commonly used sulfonamides have been prepared in this form.^{9a} In the present study a 20 per cent suspension of microcrystalline sulfathiazole was used.

summary of results of sulfonamide studies appears in the accompanying table.

The ointments were in almost all cases made up to 5 per cent of the drug. Application twice or three times a day was recommended in most of the papers dealing with ointments, as was the removal of crusts when necessary.

EXPERIMENTAL

The basis for a rational improvement in the treatment of impetigo by local application of the sulfonamides was provided by Chambers and his associates.⁸ These workers were interested for other reasons in preparing a neutral aqueous preparation of sulfonamides of much higher concentration than any available at the time.

TECHNIC OF APPLICATION

In treating impetigo locally with this preparation I employed the following technic. A drop or two of the suspension was poured onto a small gauze dressing. It was found that the water would seep into the few layers of gauze to a greater extent than did the crystals. This would concentrate the sulfonamide crystals on the surface of the dressing leaving a small white collection of pure sulfathiazole in water of the consistency of fresh mud. The actual treatment consisted simply in applying the dressing thus prepared to the skin, the bit of sulfathiazole paste being placed in contact with the lesion. The only preparation of the area was washing with ordinary soap and water, with removal of all the crusts. When necessary, the area was also shaved. One small dressing was applied to each lesion.

On removal of the dressing twenty-four hours later, the lesion was always found to be healed. As the dried dressing was removed the residual drug would come off the site of the lesion in a dust or a very friable powder.

9a These microcrystals of the sulfonamides are prepared by the Smith Kline & French Laboratories Philadelphia who supplied the material for this investigation.

Hardly ever was there any adhesion of the dressing to the site of the lesion, and in each of three lesions in which this did occur the lesion was found to be healed. There was no attempt to compare results with those of older methods of treatment in the series, since the pattern of development of impetiginous lesions is so constant under those methods.

RESULTS

Fifteen children from institutional and private practice were treated in this manner, with a total of 293 lesions. The ages of the children ranged from 1 week to 11 years. There were 2 spreading outbreaks each involving 3 children in close institutional contact with others and one pair of cases occurring in a family. The other cases, institutional or private, were single.

The observations made when the dressing was removed a day later were identical in 290 of the 293 lesions treated. Fine dry white powder would come off the skin, leaving a dry pink area corresponding to the lesion of the day before. This area would, of course, be surrounded by the usual flare. Thereafter, no further treatment or care would be given to the site of the lesion. Within a few days the epidermis would begin to grow in and the color of the flare would lighten.

In the case of the 3 lesions previously mentioned the dressing was found on the following day to adhere to the skin by a caked crust, but the base of the lesion resembled those of all the others after treatment. The area was then covered with an unmedicated dressing for another day or two to see whether the treatment had been successful. In none of these cases did the original lesion reappear or new ones develop, and the reepithelization progressed normally. It was concluded that the therapeutic result had preceded the caking and was not affected by it.

In no instance did any additional lesions develop or appear from the time of treatment of the original ones, either on the subjects or their institutional neighbors. In the case of the two outbreaks the spread ceased as of the time of the single treatment.

COMMENT

The improved results in the treatment of impetigo reported here are due only to the physical form of the agent and its chemical simplicity. Ordinary sulfonamide powders cake on lesions of impetigo for the same reason that they cake in pure aqueous suspension, presumably because the grains of powder are not naturally crystalline in shape. The microcrystalline drug maintains the separation of the crystals, assuring a much greater surface for solution into local tissue fluids and a continued distribution over the lesion.

In the case of ointments, caking is not a source of difficulty, but the serous exudate on meeting the ointment layer collects and coagulates, forming a crust which might well separate the lesion from the therapeutic agent. This would account for the necessity of frequent treatment and periodic crust removal during even the four or five day period required. The microcrystalline suspension, however, contains nothing but the drug and water, so that no barrier meets the exuding lymph or serum at the body surface. Any such exudate is directly miscible with the water of the suspension and is actually diluted by it. In fact it is planned to add a small amount of citrate solution as an anticoagulant to the water base of the sulfathiazole microsuspension if clotting should occur more frequently in the future.

Of some interest is the minimum amount of time required by the treatment. Although most of the lesions were observed twenty-four hours after treatment there is no evidence that that length of time is required. The last patient of the series, originally exhibiting 23 lesions, had the dressings removed in about sixteen hours, with the usual results. If, as would appear to be the case, we have considerably improved the physicochemical environment of the interaction of sulfathiazole and cocci, then the actual time of treatment may be considerably reduced, approaching ideally the time of ordinary serum-coccus-sulfonamide mixtures. It is planned to determine this time threshold in the next series of cases.

Finally, the complete halting of the spread of the disease from the time of treatment which has been observed thus far, is of considerable practical importance. Taken in conjunction with the single treatment required, this means that the checking and treatment of an epidemic of impetigo, even in a crowded group, is completed within an hour or so of the time treatment is begun. Under conditions of crowding the thorough washing with soap and water of close contacts and then examination of these a day later is, of course, assumed.

The importance of a more rapid cure and check of spread of impetigo from the point of view of public health need hardly be pointed out here. There are other aspects of the disease, however, which call for the most rapid control of epidemics whenever they appear. Impetigo neonatorum is admittedly important to the health of the patient, but in children past infancy the disease is generally regarded as of negligible significance to the patient's health. In view of this prevalent attitude it is worth pointing out that in each of five series of cases of glomerulonephritis¹⁰ impetigo was identified as the precursor in percentages ranging from 10 to 15. These series include a total of 650 cases in Australia, Germany and the United States, and the percentages were of the total number of cases in each series rather than of those cases in which the precursor could be identified. Two other authors who review the subject, Volhard¹¹ and Silvers,¹² bring out additional evidence of this association. Since the length of incubation of the bacteria in the skin must affect the degree of sensitization to bacterial antigens, there can be no doubt of the importance of aborting cases of impetigo as quickly as possible.

Sulfathiazole was used in these studies because of its availability and its effectiveness on both streptococci and staphylococci. Microcrystals of other sulfonamide compounds have been produced and would presumably be as effective against susceptible bacteria.

SUMMARY

A single application of a new physical form of the sulfonamides in the treatment of impetigo in my experience with the method thus far has been found to cure the lesions within a day and to stop the spread of the disease.

SULFATHIAZOLE IN ECZEMATOUS PYODERMA

SENSITIZATION REACTION TO SUCCESSIVE LOCAL
AND ORAL THERAPY REPORT OF
TWELVE CASES

MAJOR CLARENCE S. LIVINGOOD

MEDICAL CORPS, UNITED STATES ARMY

AND

LIEUTENANT COLONEL DONALD M. PILLSBURY

MEDICAL CORPS, ARMY OF THE UNITED STATES

The induction of sensitivity to various sulfonamide compounds and the possible physiologic mechanisms responsible are subjects of increasing interest and importance. This paper is a report of a reaction which we have observed in 12 patients, in whom a sensitivity to sulfathiazole was apparently induced by local application of it to diseased skin, and in whom the evidence of sensitivity appeared when the drug was later administered by mouth. These patients all suffered from various forms of eczematous dermatitis complicated by some degree of low grade secondary pyococcic infection and were treated for more than five days with 5 per cent sulfathiazole emulsion type ointment and later given sulfathiazole by mouth. A characteristic explosive type of systemic and dermatologic reaction occurred. These patients were part of a series of more than 1,000 patients suffering from various dermatoses whom we have treated with the sulfonamide compounds applied locally.

The several reports regarding the use of sulfathiazole ointment in the treatment of cutaneous pyogenic infections will not be completely summarized here.¹ In three reports some local reaction to sulfathiazole ointment was reported. Sams and Capland² observed a patient in whom the local application of sulfathiazole powder for chronic otitis externa produced an acute exacerbation. Later administration of sulfathiazole by mouth to this patient was followed by massive edema of the face and ears and a generalized erythematous macular and pustular eruption. Recently Miller³ reported that a patient with sycosis vulgaris had been given applications of 50 per cent and 25 per cent sulfathiazole ointment for a total of two weeks. Two months later the patient was given 1 Gm of sulfathiazole by mouth and within two hours the eyelids became swollen shut and an eruption appeared on the face, forearms, back, abdomen and thighs. In another study we⁴ reported on the treatment of 190 patients with sulfathiazole incorporated in bases of various types. In this paper we stated that "in a few patients with chronic eczematoid eruptions, flare-ups have been noted in conjunction with the use of sulfathiazole ointment

but no exacerbation has been noted in a patient with a dermatosis primarily due to infection." None of the patients in this series had been given sulfathiazole by mouth after local application of the drug. It was demonstrated that sulfathiazole ointment (particularly when the ointment base is of the emulsion water soluble type) is an extremely effective therapeutic agent in the treatment of impetigo, ecthyma and acute impetiginous dermatitis uncomplicated by other etiologic factors. However, it was emphasized that sulfathiazole ointment has a much less striking effect on eczematous lesions complicated by chronic bacterial infection than on acute pyoderms due solely to pyococci. Our subsequent experience in a large series of patients is in accord with this. In addition, certain limitations and contraindications to sulfathiazole ointment therapy have become apparent, and it is with these that the present paper is concerned.

The following case summaries are representative of a type of reaction which we have encountered.

CASE 1—J. T., a Negro aged 22, had had dermatitis repens on the inner surface of his right ankle, anterior to the malleolus for ten months.

Physical examination was negative except for the cutaneous lesion and moderate chronic prostatitis which was possibly a focus of infection.

There had been no illnesses except the cutaneous lesion, which had increased in size slowly and which had partially regressed on two or three occasions following various types of local treatment. Sulfonamide compounds had not been administered either locally or orally.

Bacterial culture of material taken from the lesion yielded hemolytic *Staphylococcus aureus*.

From Aug. 10 to Aug. 25, 1941, a total of fifteen days, 5 per cent sulfathiazole cream was rubbed into the lesion three times a day, followed by the application of a bandage. About 50 per cent improvement was noted after seven days, following this initial change the condition of the lesion remained stationary.

From August 25 to October 20 he was given 5 per cent ammoniated mercury ointment, azochloramid ointment, sulfated potash soaks and superficial roentgen therapy (total of 300 roentgens in divided doses). Temporary improvement occurred but was not sustained, and the patient was admitted to the hospital.

October 21 sulfathiazole was administered by mouth (1 Gm four times a day). Three hours after the first dose the patient complained of pruritus of the palms and soles, malaise and chilliness, and his temperature became elevated to 100.2 F. In a few more hours a vesicular and bullous eruption appeared which in the course of twenty-four hours, involved the hands and feet (especially the palms and soles), the face including the forehead and ears and the trunk, associated with a very definite exacerbation of the original lesion on the ankle. Administration of the drug was discontinued after the first dose. The patient's temperature fluctuated between 99 and 100.5 F for the next four days and then became normal. An interesting feature was the occurrence of an extremely pruritic erythematous, edematous vesicular patch at the site of injection of an intradermal *Staphylococcus ambiohydri* test (0.025 cc.) which had been done two weeks before. This test had previously been negative. Gradual improvement occurred with symptomatic treatment and within four weeks the skin was well including the original lesion on the ankle. The patient remained well until four months later, after which he disappeared from observation.

CASE 2—M. G., a white man aged 43, had had localized eczema with secondary pyogenic infection on the outer surface of the legs—two patches on the right leg and one on the left leg—for five months.

Physical examination was negative except for the cutaneous lesions and moderate chronic prostatitis.

Onset of the three eczematoid patches was preceded by chigger bites which had become secondarily infected. The

lesions persisted despite various types of local treatment including applications of 5 per cent sulfathiazole ointment for a period of about fourteen days two months before he had come under our observation, with moderate improvement. Definite exacerbation was noted when the patient changed from cotton to long woolen underwear. He stated that he had never taken any sulfonamide compounds by mouth.

Bacterial culture of material taken from the lesions yielded hemolytic *Streptococcus* and hemolytic *Staphylococcus aureus*.

From Jan 25 to Feb 8, 1942, a total of thirteen days, 5 per cent sulfathiazole ointment was applied three times a day, followed by application of a light bandage to hold the ointment in place. Only slight improvement was noted and the patient was admitted to the hospital.

From February 8 to 20 treatment consisted of bed rest, potassium permanganate compresses, Burrows solution (1:16) compresses, 2 per cent ammoniated mercury ointment and superficial roentgen therapy (total of 100 roentgens divided into two treatments). There was slight improvement.

February 20 0.5 Gm of sulfathiazole was given by mouth. Eight hours later the patient had a chill accompanied by elevation of temperature to 102.4 F, edema of the face and eyelids and severe generalized pruritus. Within twenty-four hours there was a severe flare-up of the initial lesions on the legs, and onset of a macular and vesicular eruption involving the face, sides of the neck, buttocks, lateral surface of the thighs, backs of the hands and the thorax occurred. The temperature returned to normal after three days and within ten days the generalized eruption had disappeared entirely. At this time the initial lesions on the legs had regressed about 50 per cent.

March 2 the patient was given 0.1 Gm of sulfathiazole by mouth. The course of events just described recurred with onset about four hours after administration of the drug. This reaction was not as severe as the first and it subsided in four days. It was followed by further improvement of the initial lesions on the legs.

From March 10 to 12 he was given sulfadiazine 0.5 Gm four times a day by mouth. After a total of 4 Gm, there was a slight exacerbation of the lesions on the legs and an elevation of the temperature to 99.2 F. Therefore the drug was discontinued.

From March 12 to 24 slow improvement of all lesions occurred with symptomatic treatment. At the time of the patient's discharge, March 24, the skin was clear except for residual erythema, scaling and hyperpigmentation at the site of the original lesions on the legs. The patient was instructed to wear long cotton underwear to prevent contact of woolen clothing with the skin, and during a period of one month's observation there was no exacerbation. Although a patch test with wool was negative, it was quite clear that a low grade sensitivity to wool was an important contributory causative factor.

CASE 3—J. Z., a white man aged 30, had had chronic impetiginous dermatitis of the hands and feet (most of the involvement on the palms and soles) for two months.

Physical examination was negative except for the cutaneous lesions, hyperhidrosis, moderate chronic prostatitis and chronic tonsillitis.

Onset occurred with a vesicopustular and patchy eczematoid eruption on the soles, the sides of the feet and the dorsal surface of the right great toe two months before admission to the hospital. This was followed one month later by scattered vesicles on the palms (id?) which was succeeded by deep pustules and eczematoid patches along the sides of the fingers. It is probable that sulfathiazole ointment had been used as local treatment about six weeks before he had come under our observation. He stated that he had never taken any sulfonamide compound by mouth.

Bacterial culture of material taken from the lesions yielded hemolytic *Streptococcus* and hemolytic *Staphylococcus aureus*.

From Dec 10 to Dec 26, 1941 5 per cent sulfathiazole cream was applied four times a day. Slight improvement occurred.

December 26 treatment with sulfathiazole by mouth was started (1 Gm four times a day). Four hours after the second dose the patient was awakened by severe pruritus of the palms and soles. His temperature became elevated to 101 F and this

was accompanied by malaise and chilliness. Within the next twelve hours an erythematous macular and vesicular eruption appeared on the face, the posterior portion of the ears, the backs of the hands and feet and the buttocks. This eruption later became eczematous, with oozing in intertriginous sites and scaling on the face, buttocks and backs of the hands and feet. There was a decided exacerbation of the lesions on the hands and feet. The elevation of temperature and the constitutional symptoms subsided in four days and the generalized eruption disappeared entirely at the end of fourteen days with about 50 per cent improvement of the primary dermatosis on the hands and feet.

Jan 8 1942 0.5 Gm of sulfathiazole was given by mouth. The course of events described was repeated except that the reaction was not as severe and the symptoms subsided within five days.

From January 18 to 21 sulfadiazine (1 Gm four times a day) was given by mouth. No reaction of any kind occurred. There was no improvement (the drug was not continued for a time sufficient for a therapeutic trial).

From January 21 to March 2 the lesions on the palms and soles slowly disappeared. At least part of the improvement was due to a tonsillectomy and a course of prostatic massage, and the patient remained well for a period of one month, after which he was lost from observation.

COMMENT

As our experience with this sensitization reaction increased, it became apparent that there were certain factors common in all of our cases.

1. Thus far the reaction has occurred only in those persons who have had a localized eczema with a secondary pyogenic element or a chronic impetiginous dermatitis which was predominantly eczematous. In all such patients one of the etiologic factors in the dermatosis, as far as could be determined, was sensitization to insect bites (chiggers), wool, shoe leather, soap, weeds or to the allergenic products of bacteria. We have not observed the reaction in impetigo, in ecthyma or in acute pyogenic complications of fungous infections or of acute dermatitis venenata. Provided the dermatitis did not become chronically eczematous.

2. The reaction is probably induced by rather prolonged application of the sulfathiazole ointment (more than five days) and becomes manifest when sulfathiazole is given by mouth. The symptoms occur following administration of a very small amount of sulfathiazole and within a period of a few hours. We do not know whether or not the local application of the drug leads to an increased sensitization of the skin as compared with the sensitization which frequently occurs following the administration of sulfathiazole by mouth. It is possible that the oral administration of sulfathiazole followed by an interval of time and subsequent use of the drug by mouth would result in the same chain of symptoms in a patient with a dermatosis of the type described.

3. The course of events was very similar in all cases: (a) the prompt development of constitutional symptoms including malaise, chilliness and elevation of temperature, (b) the local exacerbation of the lesions under treatment and (c) the generalized hematogenous "id"-like eruption, which was always pruritic and "explosive" in its onset. In many respects, the symptoms are not unlike those described by Lyons and Balberor⁶ in a recent paper (also discussed in an editorial in *THE JOURNAL*).⁵ They described a so-called sulfonamide shock representing an acquired sensitivity to the sulfonamide as the result of oral administration.

⁵ Sulfonamide Sensitivity, editorial, *J. A. M. A.* 119:1202 (Aug 8) 1942.

⁶ Lyons R. H. and Balberor, Harry. *Univ. Hosp. Bull. Ann Arbor Mich.* 7:19 (March) 1941.

of the drug, manifested on subsequent oral administration (after a five to fourteen day interval) of the same sulfonamide compound. Their evidence indicated "that approximately one third of all patients treated with sulfonamide drugs develop a sensitivity to these drugs sufficient to interfere with their subsequent use on these patients." The symptoms which they observed included elevation of temperature, chilliness, erythema, pruritus and conjunctival injection. It is probable that there are similarities in the mechanism of the reaction which they have described and the reaction which we have observed. However, it is to be pointed out that the absorption of sulfathiazole during the local treatment of the cutaneous lesions which we describe is extremely small compared to that occurring during administration by mouth. (None of our patients had a history of oral sulfathiazole therapy previous to the treatment of their cutaneous disease.) It is our opinion that when sensitization occurs on local application of sulfathiazole it does so more frequently in certain types of cutaneous disease in which pyogenic infection is a partial causative factor but not the chief one. Cutaneous tests with the chemically pure sulfonamide compound in an effort to predict reactivity are almost valueless.

4 The symptoms recur when sulfathiazole by mouth is resumed for a second and third time. It is possible that such patients might tolerate the drug eventually, that is, that "hyposensitization" could be accomplished, because in many of our cases the reactions have decreased in severity. It is not known how long the sensitivity to sulfathiazole persists, we have not had an opportunity to determine this in any of our patients.

5 We are not certain whether these patients can take other sulfonamides by mouth without reaction. Of 4 of our patients who had one reaction and were given sulfadiazine after the first reaction had subsided, 3 had no symptoms and the other one had a slight elevation of temperature and a local exacerbation of his cutaneous lesions (case 2). Recently, we have been using 5 per cent sulfadiazine ointment in the treatment of cutaneous infections, but we have not had sufficient experience to form any conclusions regarding the occurrence of this sensitization reaction in a group of patients similar to the reaction in those cases in which sulfathiazole was used. On the basis of a limited experience, it is our belief that sulfadiazine ointment probably is as effective as sulfathiazole ointment as a therapeutic agent in cutaneous infections primarily due to pyococci.

6 We have noted that, in most instances the reaction described has been followed by improvement of the primary dermatosis under treatment. We do not think that this can be attributed to the elevation of temperature, the reason is not clear, but possibly it is due to an increase in local and general immunity to the bacterial organism.

7 There have been no changes in the blood count and no evidence of liver or kidney damage in connection with this reaction.

8 It is our feeling that sulfathiazole ointment should not be used indiscriminately in the treatment of eczematous lesions complicated by chronic pyogenic infection or of chronic impetiginous dermatitis which becomes eczematous. If improvement occurs with local sulfonamide therapy, it does so in a relatively short period of time and prolonged local application is neither advisable nor necessary. It seems imperative to administer sulfathiazole by mouth cautiously to patients with the types of cutaneous disease described here if local sulfathiazole therapy has been used previously.

SUMMARY

The type of sulfathiazole reaction described here is apparently a result of sensitization to the drug induced by local application and becomes manifest after oral administration of sulfathiazole. This reaction is characteristic and has been noted only in patients who have been treated for localized eczema plus a chronic complicating infection or for impetiginous dermatitis with eczematous tendencies. The reaction has been observed in 12 patients. On the basis of an experience with more than 1,000 patients in whom local sulfathiazole therapy to the skin has been used, it is considered that (1) such therapy should not be employed for prolonged periods (more than five days), since the danger of sensitization is apparently increased thereby, (2) the indications for such therapy should be carefully considered, (3) local sulfathiazole therapy is highly effective when properly applied in frank superficial pyodermas (impetigo, ecthyma and acute pyococcal infections of superficial fungous disease dermatitis or eczema) but is decidedly less effective and productive of possible later reactions in cases of chronic eczematous processes in which sensitization to various substances, including bacteria has occurred.

HYPERSENSITIVITY PRODUCED BY THE
TOPICAL APPLICATION OF
SULFATHIAZOLE

MILTON H. COHEN, M.D.

H. B. THOMAS, M.D.

AND

A. C. KALISCH, M.D.

PHILA., PA.

The use of sulfonamides locally has progressed rapidly during the last several years. In the treatment of various pyogenic infections of the skin sulfathiazole ointment has been described in several series of cases with satisfactory results and no toxic manifestations. Sams and Capland¹ had favorable results with sulfathiazole ointment in 53 cases of cutaneous infections with no detrimental local or systemic effects. Beinbauer, Knoll and Perrin² treated 19 patients with infectious eczematoid dermatitis, with 13 instances of clinical cure and 5 of decided improvement. Winer and Strakosch³ stress the value of sulfathiazole ointment in the treatment of impetigo contagiosa and even reported excellent results with only the oral use of the drug. The Robinsons⁴ reported excellent results with the local treatment of the dermatosis of 94 patients. Strakosch and Olsen⁵ stated that topical administration of sulfathiazole is advantageous because local tissue concentration will be reached with smaller amounts and unpleasant toxic reactions are minimized.

While the profession is learning to respect the untoward reactions of this group of drugs when used by mouth or by needle, there has been no description

of reactions to the drugs when applied locally for various cutaneous disorders. The reason for the absence of reports of toxic manifestations in cutaneous disease may be that the ointment was not applied over relatively large areas of denuded surface permitting sensitization by the drug. We have recently seen 2 cases of varicose eczema of the legs with large denuded areas to which sulfathiazole ointment was applied for a short time, and in each case fever and a generalized toxic rash promptly developed which subsided on cessation of the drug. Furthermore, in both cases the rash was reproduced by ingestion of small amounts of sulfathiazole, in the second case a full-blown cutaneous reaction developed six hours after ingestion of only 8 mg ($\frac{1}{8}$ grain) of sulfathiazole.

REPORT OF CASES

CASE 1—Mrs H P, aged 58, a farmer's wife, first seen on June 15, 1942, since December 1941 had suffered from a sharply margined ulcer about the size of a quarter (24 mm) over the inner malleolus of her right leg. In April 1942 the leg became swollen and the area around the ulcer became red and weepy. The inflammation extended to the midportion of her leg, and large varicose veins were present. The left leg also showed varicosities but no ulceration or inflammation. Owing to the edema and inflammation, injection therapy of the veins was not considered, but she was advised to rest the limb and apply wet compresses. Since she was unable to follow this suggestion 5 per cent sulfathiazole ointment was applied on gauze to the inflamed area, the limb was bandaged to the knee and a supportive elastoplast bandage was applied. Four days later an erythematous patchy eruption appeared on

powders were used for the extensive generalized eruption. In a few days the rash assumed the appearance of an erythroderma, the fever subsided and after ten days a branny desquamation occurred with moderate exfoliation of the skin of her hands and feet. The Wassermann reaction of her blood was negative and other laboratory examinations were negative. Physical examination was essentially negative with the exception of the dermatologic disorder.

Fig 2 (case 2)—Varicose eczema after removal of sulfathiazole ointment.

She was discharged from the hospital July 1. The leg ulcer had practically healed and the eruption was slightly sealing and receding. On July 6 she returned for observation, and it was then noted that small crusted pustular lesions were present on both buttocks. The generalized eruption had disappeared and she was comfortable except for these small pyogenic areas. The smear from these lesions showed the presence of streptococci and a few staphylococci and she was advised to take sulfathiazole by mouth. She ingested 1 Gm of the drug and within three hours, before she had a chance to take the second dose, her skin began to burn and tingle, an erythematous rash appeared almost universally and her temperature was elevated to 102 F. The drug was stopped and the eruption progressed through the stages of erythema, papules in patchy formation, desquamation and exfoliation exactly similar to the events that followed the application of the sulfathiazole paste boot. She remained in bed at home under expectant therapy and in two weeks, after considerable desquamation the dermatitis subsided leaving a somewhat thickened indurated dermis.

CASE 2—Mrs R S, aged 64, admitted to the York Hospital July 3, 1942, complained chiefly of a generalized rash. She had suffered with varicose veins in both legs for more than twenty years and obtained relief with elastic stockings. In 1939 ulcers developed on the lower left leg and healed with difficulty under indifferent therapy. On June 15, 1942 the skin of the lower left leg became red and inflamed associated with severe itching but no ulceration. She continued her occupation as a cook but consulted her physician who applied a 5 per cent sulfathiazole ointment to the inflamed area. Within twenty-four hours a well defined weeping reaction occurred, but she continued the use of the ointment reapplying a fresh amount after cleansing the affected parts with a bland oil. After three days of such treatment a generalized eruption appeared over her whole body which did not subside after she discontinued the sulfathiazole ointment and she was referred to the York Hospital.

The eruption at the time of admission consisted of raised patchy papules with surrounding erythema. Moderate desquamation was present in the antecubital spaces, forearms and palms of the hands. Large varicose veins were observed on both legs. On the lower left leg an indurated eczematoid area was present which was crusted and moist. With mild lotions and wet compresses to the varicose eczema the generalized eruption subsided, a branny desquamation occurred and the intensity of her itching lessened. Her temperature on admission was 100 F, which subsided in forty-eight hours. On July 10, one week after her admission she was given 8 mg ($\frac{1}{8}$ grain) of sulfathiazole powder by mouth to determine whether this drug was an etiologic factor. Within six hours an intense red, itching, raised papuloerythematous eruption appeared on her face, arms, neck, back and chest. The rash

Fig 1 (case 2)—Generalized eruption resulting from topical application of sulfathiazole.

her arms, chest, back, face and both legs. Her temperature rose to 101 F and she suffered chills and malaise. She was admitted to the York Hospital on June 21. The elastoplast bandage was removed and the raw, inflamed area appeared red, glistening and clean. A little of the sulfathiazole ointment was still retained in the ulcer and surrounding skin. Wet continuous compresses of potassium permanganate (1:2,000) were applied to the left leg and soothing mild lotions and

was patchy with arcuate configuration the primary lesions being papules with an erythematous halo. There was no elevation of temperature with this reaction. On the back small crusted lesions occurred with necrotic and pustular centers. The whole picture resembled exactly what was seen on her admission and under mild expectant therapy subsided in the same manner. Two weeks after this outbreak the skin was still somewhat reddened and thick following an exfoliative process.

Serologic reaction of her blood was negative and her blood count was normal. Sulfathiazole determination of the blood twenty-four hours after the ingestion of the $\frac{1}{2}$ grain of sulfathiazole was negative. Examination of her urine also gave negative results. Physical examination was inconsequential except for the varicose veins, varicose eczema and eruption. Patch tests with 5 per cent sulfathiazole ointment, powdered sulfathiazole, petrolatum, hydrous wool fat and powdered sulfanilamide were negative. There is no personal or family history of hay fever, asthma, urticaria or other cutaneous lesions. She is the mother of 9 children, none of whom have ever shown any allergic manifestations.

COMMENT

In an analysis of the events that occurred in these 2 cases many problems of drug sensitivity and toxicity are aroused that so far are not clearly understood. Sulfathiazole and its allied compounds have been in general use for too short a time for all its manifestations and its dangerous possibilities to be clearly and scientifically appraised.

In our first case the possibility of sulfathiazole sensitization was not recognized until after the drug was readministered by mouth. After the use of an occlusive bandage and a four day interval, a generalized erythroderma developed which resembled a type of eruption already described as resulting from the ingestion of sulfathiazole.⁶ Two weeks later, after the ingestion of 1 Gm, the former eruption quickly reappeared in an aggravated form. In the second case sulfathiazole ointment was applied and in three days a generalized eruption occurred, after an interval of ten days 8 mg ($\frac{1}{8}$ grain) of sulfathiazole was administered orally and an eruption appeared within six hours which resembled in every respect the characteristics of the original rash and was identical with the one seen in case 1. The whole sequence of events in these 2 similar cases must be the result of cause and effect, and coincidence can probably be eliminated.

The danger of arousing a latent sensitivity by the ingestion of sulfathiazole has received considerable comment by many investigators. Lyons and Balberor⁷ comment that the high incidence of fever associated with the readministration of sulfathiazole strongly suggests that the use of the drug is accompanied by more danger than was formerly considered. They believe that sulfathiazole when introduced into the body may develop antigenic properties which in certain instances produce a state of hypersensitivity that is manifested by a fever response. They suggest that the relative specificity of the reaction points toward the antigenic nature of the drug in spite of the fact that sensitivity to any drug cannot be demonstrated by scratch, patch or passive transfer studies. They furthermore stress that the incidence of the reaction is enhanced by an

interval between the courses in contrast to the continuous administration of the drug. Stiles⁸ reports 4 cases in which apparently hypersensitivity developed even after small doses of sulfathiazole. In each case after sulfathiazole had been discontinued the administration of a single 0.5 Gm tablet was followed by nervousness, chills, malaise and fever. Shavin,⁹ Davidson and Bullowa¹⁰ and Winsor and Burch¹¹ all emphasize the allergic potentialities of sulfathiazole and warn against careless administration after a lapse of treatment. Our experience has been somewhat unique, for in our cases sensitization of the skin was aroused by the topical administration of the drug and was reactivated after an interval by the ingestion of 1 Gm in 1 case and only 8 mg in the second case.

One can only speculate how many patients use the sulfonamides either locally or generally for a short time or in small quantities and do not progress to clinical evidence of toxicity. At some later date when large doses are necessary they will probably show the classic symptoms of an untoward reaction and will not be able to benefit from the remarkable bacteriostatic properties of these drugs.

Combes and Cañizares⁶ quote the Suttons as advising the use of sulfanilamide in cases of "eczema" of the legs which they believe is due to a remote focus of streptococcal infection. They also state that the drug is of value in stopping the spread of acute or subacute infectious eczematoid dermatitis. However, in both of our cases the varicose eczema had been present for a long time and a great variety of local treatments had been applied without the production of an infectious eczematoid dermatitis and no generalized eruption had appeared until sulfathiazole had been applied locally and ingested internally. We therefore feel that the generalized eruption was not an eczematoid dermatitis but a sensitization process caused by the local application of sulfathiazole.

Richter¹² studied 79 cases of generalized exfoliating erythrodermas of which 38 were associated with eczema. He divided his cases into three main groups: (1) those caused by internal disturbances, (2) those due to advanced age and (3) those presenting demonstrable external nonaccutaneous idiosyncrasy from contact with various chemical substances. From our experience sulfathiazole ointment can be considered a noxious chemical substance which can give rise to cutaneous idiosyncrasy.

In view of the absorption with the possibility of toxic reactions, it is urged that the profession refrain from using sulfathiazole ointment in those minor conditions in which less harmful drugs are completely adequate. This form of the drug should probably never be used over areas of moderate to large size in which there is danger of arousing sensitization of the dermis. It is well recognized by all authorities that sensitization to the sulfonamides may be permanent. This property makes the use of the drug either locally or generally for minor or self-limited conditions a dangerous practice because it may forever prohibit its administration when serious bacterial disease occurs at some future date.

CONCLUSIONS

1 Two patients with varicose eczema were treated locally with 5 per cent sulfathiazole ointment with the production of a generalized eruption that was reproduced after the administration of small doses of sulfathiazole by mouth

2 We believe that the topical application of sulfathiazole can arouse a hypersensitivity resembling an allergic phenomenon and that this hypersensitivity can be affected by continuing the use of the drug either locally or by ingestion

3 We feel that sulfathiazole is potentially too dangerous a drug to use indiscriminately in mild ailments, and it is very possible that the intermittent use of this drug may produce dangerous reactions

4 If sulfathiazole is continued after an interval of cessation, only minute doses need be given to ascertain whether sensitization has occurred

5 The older methods of treatment of varicose eczema and varicose ulcer—vein injection, gelatin boot, rest and wet compresses, roentgen therapy and the like—should always be tried before sulfathiazole therapy is instituted

CUTANEOUS HYPERSENSITIVITY TO TOPICAL APPLICATION OF SULFATHIAZOLE

ALFRED L. WEINER, M.D.
CINCINNATI

Local application of the sulfonamide drugs in the management of various dermatologic and surgical conditions has by this time attained a deserved popularity. Sulfathiazole and its sodium salt, chiefly in crystalline or ointment form, have proved to be the most widely used and perhaps the most efficacious in this respect. Numerous reports attest both the popularity and the effectiveness of these medications when employed in the therapy of such diverse conditions as impetigo, ecthyma, pyoderma, furunculosis, certain cases of acne vulgaris, sycosis barbae, infectious eczematoid dermatitis and in secondarily infected cutaneous lesions of many other types.¹ Certain ophthalmologic diseases have also been successfully treated by this method.²

Hypersensitivity to direct application of sulfathiazole to the skin has been encountered in isolated instances. The resultant reaction has been in the form of chemical, vesicular or vesiculopapular dermatitis at the onset. A systemic reaction has seldom been observed in this regard (the blood levels are not significantly affected), but this may occur provided a sufficiently large area of the surface has been treated and especially if the treated areas have been denuded of surface epithelium, as in extensive burns for example.

The incidence of sensitization of sulfathiazole applied locally is probably low. Keeney, Pembroke, Chatard and Ziegler,³ Pillsbury, Wammock, Livingood and

Nichols,⁴ Winer and Strakosch,⁵ and Glicklich⁶ failed to observe this phenomenon in relatively large numbers of patients treated with sulfathiazole ointment. Sams and Capland, however, noted 1 example of clinical hypersensitivity in their report. The patient experienced an exacerbation of dermatitis about the ears following the use of sulfathiazole powder on two separate occasions. Patch tests with sulfathiazole crystals were negative, but the authors concluded nevertheless that the patient was hypersensitive.

Miller⁷ observed 2 instances of cutaneous reactions to 50 per cent sulfathiazole ointment. In one of these the eruption recurred when the drug was given orally. He also observed mild vesicular eruptions following the application of 10 per cent sulfathiazole with recurrences when the ointment was later reapplied. Although patch tests with sulfathiazole were not performed

Fig. 1 (case 1).—Vesicular and papular dermatitis of the neck, resulting from hypersensitivity to sulfathiazole ointment.

Miller implied that the reactions were the result of absorption and warned against the possible danger of sensitizing the patient by the local application of sulfathiazole and thus precluding future oral administration for systemic infections.

Instances of sensitization to sulfathiazole applied topically (wherein the diagnosis has been established by patch testing), apparently have not been recorded in the literature. The complex nature of the ointment bases used in some commercial sulfathiazole preparations has added to the problem of accurately determin-

The photographic illustrations in this report were made by Dr. Daniel J. Kandel.

ing such reactions. It seems probable, however, that cutaneous hypersensitivity to sulfathiazole powder and ointments will appear with increasing frequency as these therapeutic agents gain even more general acceptance. In view of these circumstances the following experiences should be of interest.

Fig. 2 (case 2)—Positive reaction with sulfathiazole crystals

REPORT OF CASES

CASE 1—J. E., a white man aged 55, was referred to me by Dr. Aaron Kanter for the treatment of a basal cell carcinoma affecting the back of the neck. Following confirmation of the diagnosis microscopically, the lesion was treated by means of the administration of roentgen radiation with a total of 6 erythema doses (2,100 roentgens) given. Erythema was effected within ten days and rapid sloughing of the carcinoma took place. Healing began about three and one-half weeks after the beginning of treatment and a proprietary ointment containing 5 per cent sulfathiazole was prescribed to prevent the occurrence of secondary infection. About twenty-four hours after the initial application the patient experienced burning and pruritus, and the next day a severe papular and vesicular eruption was observed in the areas of the healing carcinoma and surrounding skin (fig. 1).

The sulfathiazole ointment was discontinued and the dermatitis treated by means of bland moist compresses and lotions. Recovery was prompt and uneventful. Patch tests were then performed with the results shown in the first part of table 1. Several control tests with the substances employed in the preliminary tests were negative. The manufacturers of the sulfathiazole ointment⁸ were consulted and the various ingredients contained in the preparation were given as follows: sulfathiazole 5 per cent, duponol PC 1 per cent, steryl alcohol 10 per cent, cetyl alcohol 3 per cent, spermaceti 10 per cent, glycerin 10 per cent, sodium ethyl mercuriothiosalicylate (merthiolate) 0.005 per cent and sufficient water.

The final patch tests were then performed with results shown in the last part of table 1.

From the clinical course and the results of the patch testing, it was concluded that the patient was hypersensitive to sulfathiazole and sodium sulfathiazole in crystalline, solution or ointment form. An interval of about twenty-four hours occurred between the time of the first application of the ointment and the appearance of the patient's dermatitis. Since neither the patient nor his physician were aware of previous applications of sulfathiazole to the skin, it appeared that a period of twenty-four hours was necessary for the development of hypersensitivity (sensitization period?) in the patient.

CASE 2—Mrs. M. S., aged 42, white, a housewife, was referred to me through Dr. Francis X. Siegel because of the presence of an erythematous papulovesicular eruption of the eyelids. The dermatosis had been present for four weeks. For six months previously the patient had been treated by several ophthalmologists for corneal ulcers. A variety of solutions and ointments including 1 per cent yellow oxide of mercury, sulfathiazole ointment, zinc-boric acid drops and an ointment containing zinc oxide and ichthammol had been employed. Only the sulfathiazole ointment had been employed during the six weeks preceding the onset of the dermatitis.

In view of the characteristics and localization of the eruption, dermatitis resulting from sensitivity to nail lacquer was suggested. On inquiry it was learned that the patient had used this cosmetic over a period of several years. Various other substances were considered as possible causative agents, but except for the nail lacquer and eye medications these seemed unlikely.

Treatment consisted of removal of the patient's nail lacquer, elimination of all previous local therapy and administration of fractional doses of roentgen radiation. Dilute Burrow's solution compresses and zinc oxide paste were applied locally. In response to this treatment the lesions about the eyelids subsided in about two weeks. Patch tests were then performed, the results of which are given in table 2.

The patient was then advised to reapply her nail lacquer to exclude clinical hypersensitivity in the presence of negative patch tests.⁹ No recurrence of the dermatitis took place. Several weeks later when sulfathiazole ointment was again applied to the eyelids a definite flare up of the eruption occurred. The conclusions drawn from the patch testing and clinical course were that the patient was hypersensitive to sulfathiazole and to sodium sulfathiazole in crystalline, solution and ointment form.

CASE 3—Mrs. P. M., aged 28, white, was referred for the treatment of a generalized dermatosis by Dr. Abbott Y. Wilcox. The eruption began following the application of adhesive plaster

TABLE 1—Results of Patch Tests in Case 1

Substance	Result	Substance	Result
Preliminary Tests			
Sodium sulfathiazole crystals	2 plus	Sodium sulfathiazole solution (5%)	2 plus
Sulfathiazole ointment (5%)	2 plus	Toilet soap used by patient	Negative
Final Tests			
Steryl alcohol	Negative	Glycerin	Negative
Cetyl alcohol	Negative	Spermaceti	Negative
Duponol	Negative	Sulfathiazole ointment	2 plus
Merthiolate	Negative	Sulfathiazole crystals	3 plus
Sodium sulfathiazole crystals	3 plus		

TABLE 2—Results of Patch Tests in Case 2

Substance	Result
Sodium sulfathiazole crystals	3 plus
Sulfathiazole ointment (5%)	2 plus
Sulfathiazole crystals	3 plus
Sodium sulfathiazole solution (5%)	3 plus
	(delayed reaction)
Nail lacquers	Negative
Zinc boric acid eye drops	Negative
Zinc oxide ichthammol ointment	Negative
Murine	Negative
Eye drops (unidentified)	Negative

for the immobilization of a sprained ankle, as a characteristic erythematous, papulovesicular adhesive plaster dermatitis, about this member. Despite removal of the plaster, the lesions spread rapidly to the upper part of the leg. A secondary infection supervened and a commercial 5 per cent sulfathiazole ointment¹⁰

⁹ Hollander, Lester. Nail Lacquer Dermatitis. J. A. M. A. 115: 1714 (Nov. 16) 1940.

¹⁰ Sulfathiazole ointment prepared by Eli Lilly & Co., Indianapolis, was used in this instance. The ingredients of this preparation were listed as follows by the manufacturer: White beeswax, white petrolatum, anhydrous lanolin and sulfathiazole.

⁸ The preparation used was Pragnasul manufactured by the Smith Kline & French Laboratories, Philadelphia.

had then been applied. After several days the dermatitis appeared on all the extremities, and there were patches on the trunk and neck.

The diagnosis of contact dermatitis from sulfathiazole beginning as an irritant (adhesive plaster) dermatitis was made. Treatment consisting of superficial roentgen radiation, dilute boric acid compresses and a bland "shake" lotion was instituted. The use of the sulfathiazole preparation was discontinued.

TABLE 3—Results of Patch Tests in Case 3

Substance	Result
Sulfathiazole crystals	3 plus
Sodium sulfathiazole crystals	3 plus
Sulfathiazole ointment (5%)	3 plus
Ingredients of ointment base	Negative
Nylon	Negative

TABLE 4—Results of Patch Tests in Case 4

Substance	Result
Sulfathiazole crystals	4 plus
Sodium sulfathiazole crystals	3 plus
Sulfathiazole ointment (5%)	3 plus
Sulfathiazole solution (5%)	2 plus
Sulfanilamide crystals	Negative
Sulfadiazine crystals	Negative
Ingredients of sulfathiazole ointment base	Negative
Sulfapyridine crystals	Negative

The patient recovered from the dermatosis within three weeks without sequelae, and patch tests were then performed, with the results given in table 3.

A severe irritant dermatitis was observed in the areas in which adhesive plaster had been applied to hold the patch tests in place. Conclusions were that the patient was unduly sensitive to the adhesive plaster and hypersensitive to sulfathiazole and sodium sulfathiazole crystals and to sulfathiazole ointment.

Determination of group as opposed to specific hypersensitivity was investigated by means of patch tests with various other sulfonamide drugs. The reactions to powdered sulfanilamide, sulfapyridine and sulfadiazine were repeatedly negative, whereas those to sulfathiazole and sodium sulfathiazole were persistently positive.

CASE 4—Miss M. B., aged 39, white, referred by Dr. Cyril E. Schrimpf, had had a chronic recurrent eczematous eruption affecting the external ears for the past several years. Recently some roentgen therapy had been given in combination with applications of sulfathiazole powder. At first the results of treatment were good. After several weeks, however, the external ears became edematous, reddened and oozing. A papular and vesicular eruption appeared in the surrounding areas with subsequent spread to the neck, face, antecubital fossae, anterior part of the chest, abdomen and back. The severity of the dermatitis necessitated hospitalization.

Treatment was initiated by removing the sulfathiazole powder and the application of soothing compresses and lotions. Recovery was prompt and complete within two weeks.

Patch tests were performed, and the reactions recorded in table 4 were observed.

The obvious conclusions were that the patient was hypersensitive to sulfathiazole and sodium sulfathiazole in crystalline and ointment form and that the reactions were specific.

COMMENT

The cases described herein presented cutaneous eruptions associated with the use of sulfathiazole ointments and characteristic of contact dermatitis in every respect. The lesions began as papules or vesicles and proceeded to eczematization with oozing, erythema, crust formation, desquamation and healing without scarification. The diagnosis was established in each instance from the history and by patch testing and in 1 instance by means of a flare-up test. Control patch tests were performed on nonsensitive persons to exclude the possibility of primary irritant rather than a sensi-

tization effect for sulfathiazole and sodium sulfathiazole crystals. Attempts to discover allergenic tendencies among the various ingredients of the bases for the sulfathiazole ointments in cases 1, 3 and 4 were unsuccessful. In 3 cases repeated applications of the drug were apparently necessary before sensitization occurred. In case 1 the reaction was noted within twenty-four hours, so that the ointment had been used only a few times. Investigation in cases 3 and 4 disclosed that the hypersensitivity was specific for sulfathiazole and its sodium salt, since patch tests with other sulfonamide drugs failed to elicit reactions. The lesions subsided promptly in each case when applications of the sulfathiazole were discontinued.

SUMMARY AND CONCLUSIONS

1 The diagnosis in 4 cases of cutaneous hypersensitivity to sulfathiazole and sodium sulfathiazole and ointments containing these substances was established in each instance by means of patch testing. From these procedures, the ingredients of the ointment bases of two commercial sulfathiazole preparations were not implicated as causative allergens.

2 The dermatitis occurred in each case as a characteristic contact dermatitis which disappeared when the sulfathiazole preparations were no longer applied.

3 In view of the popularity of therapy with topical applications of sulfathiazole and the relatively few recorded instances of cutaneous hypersensitivity, it is probable that the incidence of this phenomenon is low.

CUTANEOUS MELANOMAS

A CLINICAL STUDY OF SIXTY CASES

J. R. DRIVER, M.D.

AND

DONALD N. MacVICAR, M.D.

CLEVELAND

This report is based on a clinical study of 60 cases of cutaneous melanoma. Thirty-five were seen in private practice and 25 are from records of the departments of dermatology and syphilology and of surgery of the University Hospitals and represents all of the patients between the years 1921 and 1941, a period of twenty years.

In the treatment of few pathologic conditions is there such pessimism and divergence of opinion as in that of cutaneous melanoma. This is due to the generally confused ideas of the average physician concerning pigmented moles and their relation to malignant growths, the highly malignant nature of melanomas, their tendency to metastasize early and the generally unsatisfactory results obtained from various treatment procedures. Nevertheless it is true that lack of diagnostic skill and delay in the institution of adequate treatment have many times contributed to the poor results.

PRECURSOR LESIONS

The great majority of cutaneous melanomas arise from pigmented junction type nevi in the skin. In color these nevi vary from slate blue to bluish black or various shades of brown to jet black with lighter

Prof. C. N. Ienhart permitted the authors to review and use the records of the surgical department.

From the Department of Dermatology and Syphilology of the Western Reserve University School of Medicine and the University Hospitals.

Read before the Section on Dermatology and Syphilology at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1942.

and darker shades often present in the same lesion. These precursor lesions are usually smooth and flat but occasionally may be raised with a verrucous or wrinkled surface and are nearly always soft. There is scarcely any person who does not have several of them on his body, yet the number which become malig-

Fig 1—Melanoma of eighteen months duration on the anterior surface of the left leg of a man aged 48. Developed in a black mole present since birth and irritated by garter. A mid thigh amputation was performed. Regional lymph nodes were not clinically involved and dissection was refused. He has remained clinically free from metastases for fourteen months. Note daughter lesions in surrounding skin and black pigmented nevi on other leg.

Fig 2—Melanoma in a Negro aged 54 with metastasis to the regional lymph nodes in the groin and general dissemination as revealed by roentgenograms of the lungs.

nant is extremely small. They should not be confused either with the soft elevated smooth or warty and sometimes hairy pigmented intradermal nevus ("common mole") or with the raised, hard, pigmented intra-epidermal nevus (fibrous nevus).

In 48, or 80 per cent, of the cases there was a history of a previously existing pigmented lesion. In 25, or 41.7 per cent, a history was obtained of a pigmented mole being present since birth, while in 23, or 38.3 per cent, a pigmented lesion had developed later in life and had been present from eight months to thirty-two years prior to evidence of malignant change.

The nevi present since birth were brown, brown-black, slate blue, bluish black or black. Most of them were smooth, soft, flat macular or plaque-like. Those which developed later in life were more likely to be flat macular lesions, principally black or bluish black. It is our impression that the soft flat slate blue, bluish black and black moles are the most dangerous. Also those developing later in life are more apt to become malignant and, as has been pointed out by Traub and Keil,¹ show a tendency to metastasize earlier.

Fig. 3—Developed from a flat slate blue nevus on the sole of the foot. No change in the nevus was noted before metastasis occurred. The patient gave a history of irritation by a nail in his shoe eight months previously. No treatment was given. He died within two years.

LOCATION OF LESIONS

Melanomas may occur on any part of the body, but statistics generally reveal that they predominate on the lower extremities and on the face. In this series 22, or 36.7 per cent, were on the lower extremities. Of these 10, or 16.7 per cent, were on the soles of the feet, 4 were on the dorsum of the feet or on the toes, 6 were on the legs and 2 were on the thighs. In 25 cases, or 41.7 per cent, the lesions were on the head, 19 of these being on the face, 5 on the ears and 1 on the scalp. There were 7, or 11.7 per cent, on the upper extremities. There were 2 cases presenting involvement of the nail bed—the melanotic whitlow of Hutchinson—and in 2 others the site of the lesions was the skin of the fingers. The arms were involved in 3 instances.

In only 6 cases, or 10 per cent, were the lesions on the trunk.

ROLE OF TRAUMA

The role of trauma as a causative factor in the transition from a benign pigmented nevus to a malignant melanoma has been emphasized by many writers. The location of the majority of melanomas on the feet, face and ears, where trauma is most likely to occur is strongly suggestive. In 35, or 58.3 per cent of the cases, there was a history of previous trauma. The following causes were the most frequently encountered: bruises, cuts from shaving, scratches, picking of lesions, a bruise from a nail in a shoe, the wearing of shoes in the presence of a pigmented mole, incomplete removal of a pigmented nevus, the application of various caustics, previous roentgen treatment and electrolysis.

Fig 4—Melanoma showing generalized metastases in a man aged 49. Ten months previously he stubbed his right great toe. A bluish discoloration developed under the nail followed by extension into the skin of the toe. Amputation of the toe was followed by the appearance of nodules along the course of the saphenous vein.

There was no significant difference in the sex incidence, there being 33 males and 27 females. The youngest patient was 3 years of age and the oldest 78. Two thirds of the patients were over 40 years of age. Nine of the 60 patients were over 70 years of age. There were 2 Negroes in the series.

SYMPTOMS OF MELANOMA

Melanomas include tumors called malignant melanoma, melanocarcinoma, melanoepithelioma, nevocarcinoma, melanoblastoma and melanosarcoma. As to whether nevus cells and melanoblasts are ectodermal or mesodermal in origin is not important from the clinical standpoint, for there appears to be no particular difference in the degree of malignancy of the various types. However, it is well known that the well

differentiated tumors are the most dangerous because of the tendency to early metastasis.

The first change in the transition from a benign pigmented melanotic nevus to a melanoma is most likely to be an increase in the size of the lesion by peripheral extension and by an increase in pigmentation. A flat

Fig 5—Metastatic nodules in the kidney revealed at autopsy.

Fig 6—Melanoma on the foot of a man aged 25 developed in a flat brown mole of five years duration. The tumor appeared in six months following application of acid to remove the mole.

lesion may become raised and indurated, and thus is followed by bleeding, ulceration and the development of fungoid tumor masses. Radiating projections of pigment may be seen in the surrounding normal skin and indicate local dissemination. Sometimes the first

evidence of malignancy is the development of a single nodule in the center or at the edge of the nevus, or the appearance of nearby daughter lesions. An increase in pigmentation is an early warning sign and may precede the development of a nodule or infiltration of the base by many months.

Metastasis occurs comparatively early. Rarely it may even occur before any change in the primary lesion is detected. Pack and Adair² found that in two thirds of the cases of melanoma of the skin in which the regional nodes were dissected, but were not palpable prior to operation, minute foci of metastatic melanoma were discovered.

Dissemination may occur by way of the superficial lymphatics of the skin, in which case nodules or pigmented areas develop in the neighboring skin. If spread is by the deep lymphatics, the regional lymph nodes become enlarged, discrete and hard. More frequently than in any other type of malignant condition, dissemination may be through the blood stream with metastatic growths appearing in any part of the body. Obviously, such conditions are hopeless. Melanin can be demonstrated in the urine in many cases in which metastases have developed.

PROPHYLACTIC TREATMENT OF PIGMENTED MOLES

Concerning the treatment of pigmented moles, opinions vary from the removal of no moles to the removal of all of them. However there is general agreement

Fig. 7—Excision of the lesion and heavy radium irradiation to the site of operation in addition to dissection of the regional lymph nodes did not prevent generalized metastasis.

among authors that if pigmented nevi are to be treated at all they should be thoroughly destroyed or excised, with a liberal margin of healthy tissue.

DeCholnoky³ advises surgical removal of pigmented moles on the feet and irritated areas. Adair⁴ believes that the best treatment for these lesions in the quiescent state is by simple careful excision with the scalpel, caution being taken in going wide of the lesion in every direction, even going down to fascia in most instances. He considers this procedure good prophylactic cancer surgery and makes

the statement "I have not witnessed any recurrences of the quiescent melanomas when this procedure is carried out."

Traub,⁵ in discussing the junction type of melanotic nevus, states "Thus far, none of the marks I have removed for diagnostic study, regardless of the size of the excision, have later given rise to a tumor of malignant character or metastasis to nodes or other

Fig. 8—Extensive metastasis to the left lung.

tissue. This proves that the junction nevus is a benign lesion. However, it is the one lesion that should not, in my opinion, be treated by repeated solid carbon dioxide applications or frequently repeated desiccation."

Butterworth and Klauder⁶ believe that it is not practical to remove all pigmented lesions of the skin but advise prophylactic removal of those on the head and feet. Klauder⁷ states that "Thorough destruction, including healthy tissue surrounding the lesion and beneath it, by means of the electrocautery, electrodesiccation or surgical excision, affords the safest means of removing pigmented nevi. The nevus should be thoroughly destroyed in one operation. To treat these lesions by painting with acids, by applying carbon dioxide snow, by electrolysis, strangulation by applying a string around a pedunculated lesion or any treatment given at short intervals are dangerous procedures which constitute irritation which affords opportunity for malignant change."

Baxter⁸ advised surgical excision with a liberal margin of healthy tissue, and if histologic examination shows that the lesion is malignant the regional lymph nodes should be removed and a capsule of radium left in the wound. Becker⁹ recommends excision for biopsy

study of suspicious pigmented lesions and believes that metastases are not caused by this procedure. Biopsies result in early diagnosis and treatment and thus improve the prognosis. Farrell¹⁰ believes that early radical surgical removal of any type of nevus subjected to trauma, including about 4 cm. of normal skin and the subcutaneous tissue, is the only means of reducing the high mortality rate of melanomas.

Taussig and Torrey¹¹ state that the impression that it is dangerous to remove, by almost any method, the warty or hairy type of pigmented nevus is erroneous. If the nevus is of the smooth blue-black type, they recommend that it be removed by wide surgical excision or by electrodesiccation. Or one may elect to leave it alone with a warning to the patient that it should be removed immediately if it increases in size.

Anderson and Simpson¹² advise the removal of pigmented moles if located on areas likely to be chronically irritated. Their methods consist of wide surgical excision alone, roentgen rays or radium in a massive dose alone or in combination with surgical excision and the careful thorough destruction of such lesions by electrodesiccation. In an experience of over twenty years they have not seen a malignant condition develop as a result of their procedures.

Adams,⁴ in discussing the treatment of pigmented moles, says that one group of physicians advise leaving them all alone. He further states that "The second

of our 400 cases that the electric needle applied with good intent but without sufficient accuracy, is the one trauma responsible for as much wild growth as any other form of injury." He recommends simply careful scalpel dissection, caution being taken in going wide

Fig. 10—Melanoma on the breast of a man aged 48 showing the development of nodules in a flat pigmented black nevus present since birth. An increase in pigmentation was the first symptom. The lymph nodes were not clinically enlarged. Wide scalpel excision of the lesion including the deep fascia and block dissection of the axillary lymph node were performed. Generalized dissemination resulted in death two years later.

Fig. 9—Metastasis to the mesentery. Autopsy also revealed metastasis to the heart, brain, kidneys and other organs.

group is composed of men, some of whom are dermatologists. They attack the black mole with the electric needle. For this type of therapy, I have less than meager regard. In fact, I am convinced from a study

of the tumor in every direction, even going down to fascia in most instances in cases of quiescent melanomas.

Dermatologists have also been blamed by others for the use of electrolysis and the application of solid carbon dioxide on melanotic nevi, but it is our belief that, as a group, the dermatologists are by training and experience better qualified than any other group to distinguish between benign and potentially malignant nevi. Moreover, if they are to be treated, they recognize the importance of their thorough destruction either by the actual cautery, electrodesiccation or complete scalpel excision.

Our practice has been to remove pigmented junction type nevi for prophylactic and diagnostic purposes if located on areas subjected to chronic irritation. This has been done by scalpel excision with a margin of approximately one-half inch of healthy tissue, including the subcutaneous tissues. In some instances thorough destruction by the electrocautery or electrodesiccation has been employed. Recurrences or dissemination of quiescent pigmented nevi have not been seen by us following these methods. We agree with Ewing¹³ that if recurrence occurs following the excision of a mole, the lesion was already malignant before it was excised.

In our opinion, these lesions should not be treated by irradiation, by the application of caustics or solid carbon dioxide, by electrolysis or by any method requiring repeated treatments. Experienced clinical judgment is of the utmost importance.

TREATMENT OF MELANOMA

It is common knowledge that unless melanomas are adequately treated before metastasis has occurred, the prognosis is extremely grave. What constitutes ade-

quate treatment has resulted in much controversy. Should radiation therapy be employed alone? Should radiation be combined with surgical measures or should surgery alone be used? Is electrodesiccation the method of choice in treating the primary lesion? Should the regional lymph nodes be treated when there is no clin-

Fig. 11—Melanoma in a woman aged 73. A flat brown mole had been present all her life. Six months before she was seen black pigment appeared in the lesion followed by elevation and bleeding. Surrounding pigmentation had always been present. The lesion and surrounding pigmentation was destroyed by the electrocautery followed by irradiation with roentgen rays in a dosage of 6 000 roentgens. She has remained well for more than five years.

ical evidence of their involvement? These are all questions that require sound and experienced clinical judgment to answer.

Butterworth and Klauder⁶ recommend excision of the primary lesion by means of electrosurgery, including about 3 cm. of skin beyond the margin of the lesion. This is followed by heavily filtered high voltage roentgen therapy to the field of operation, as well as to the lymphatics draining the area and to the regional lymph nodes. Of 40 patients traced, 14 were living at the time the report was made. In 8 of them it was for less than three years, while 6 were alive from forty-one months to one hundred and one months.

De Chonoky³ advises wide surgical excision of the primary lesion with the underlying fascia and the surrounding subcutaneous tissue followed by dissection of the regional lymph nodes. He recommends amputation in melanomas of the fingers, toes and feet followed by dissection of the lymph nodes.

Adair⁴ reported a series of 400 cases from the Memorial Hospital in New York. In only 105, or about 25 per cent, of the patients was there a possible chance of cure. Of these, 70 had been treated more than five years, and 23, or 33 per cent, had survived. All 70 patients had been treated by surgery alone or by a combination of surgery and irradiation. In a group of 245 patients showing recurrences at the time of treatment, only 7, or 2.8 per cent, were presumably cured. He states that the results of irradiation alone were disappointing, that it nearly always fails and is indicated only for palliation in cases of hopeless involvement. On the other hand, Anderson and Simpson¹² believe that massive roentgen therapy by improved methods is superior to other forms of therapy.

More than twenty-five years ago Broders and McCarty¹⁴ advised radical surgical excision of the primary growth and dissection of the regional lymph nodes.

Taussig and Torrey,¹¹ in a review of 35 cases, concluded that melanomas can be cured if they are removed early enough by radical surgical excision or thorough destruction by electrothermic means.

When the growth is believed to be local, MacKee and Cipollaro¹⁵ prefer wide, deep surgical excision to the muscle, including the aponeurosis. The width of the excision should be greatest at the bottom in order to include malignant cells that may extend down and out. They state that it may be wise to apply a lethal dose of roentgen rays or radium before excision but that irradiation is of no help after metastasis has occurred.

In the period of twenty years covered by this report, various treatment methods have been employed. For the primary lesions, these have included electrothermic destructive procedures, scalpel excision and amputation in some cases in which the lesions were on the extremities. Irradiation, with roentgen rays and radium, was applied to the operative field in some instances. Irradiation of metastatic involvement of the

Fig. 12—A man aged 52 when first seen had generalized blood borne metastasis resulting from a melanoma on the left ankle. A flat brown black nevus had been present since birth. No treatment was given. He died three months later.

nodes failed to prevent further dissemination and death in every instance in which it was used including those in which surgical dissection was also done.

14 Broders A. C. and McCarty W. C. Melanoepithelioma. A Report of 70 Cases. *Surg. Gynec. & Obst.* 23: 28-32 (July) 1916.
15 MacKee G. M. and Cipollaro A. C. Cutaneous Cancer and Pre-cancer. New York. American Journal of Cancer 1937 pp. 147-153.

As a rule, dissection of lymph nodes was not performed unless there was clinical evidence of their involvement. Criticism of this procedure may be justified, but we would like to point out that in the practice of the dermatologist a larger proportion of the lesions are earlier types of melanomas than those seen by the surgeon or radiologist. In fact in many instances lesions that were proved microscopically to be melanomas were clinically only suspicious. For this reason the cures obtained by experienced dermatologists are in general better than those of the surgeon whose patients usually have a far advanced condition when he is called on to treat them. In our series of 60 patients, out of the group of 25 from the surgical records at the University Hospitals, only 2 were known to be living more than five years. Twelve of these 25 had regional or general metastases when first seen. In 6 instances, metastases, while not clinically present when first seen, developed in from seven to sixteen months. All 18 patients are known to have died of their disease. Seven had no nodes clinically present. Two have been well for seven and eight years respectively, 2 were clinically free from disease when last seen one and one-half years after treatment, and 1 is living with metastases. Two have since died of metastasis and 1 could not be followed.

By comparison, it is found in the other group of 35 cases seen in dermatologic practice that 31 patients had no clinical evidence of metastasis when first seen. Of these, 3 had metastases later and died in less than two years. Nine are living but have been treated less than five years, and 17, or 56.7 per cent, of this group without clinical metastasis when first seen have lived from seven to eighteen years without recurrences. In 2 instances follow-up was not possible. Four patients showing metastases when first seen have all died of their disease.

In the latter group we find a high percentage of cures because early treatment was instituted before metastases had occurred. Our experience has shown that the method of treatment is not so important as long as the melanoma is completely surgically excised or thoroughly destroyed. Wide scalpel excision was performed in the majority of instances, while electrodesiccation or the electrocautery was employed chiefly in early clinically suspicious lesions that were small in size. Follow-up irradiation to the operative field with filtered roentgen rays, with Coutard technic in doses of 5,000 to 8,000 roentgens, was employed in 6 cases in this group. As to whether irradiation in this manner should be used is a question of clinical judgment to be decided individually in each case.

The diagnosis of melanoma was made by histologic examination in 58 of the cases. In 2 that presented widespread general metastases the diagnosis was made clinically.

SUMMARY AND CONCLUSIONS

Of a series of 60 patients with melanomas, a group of 25 patients seen in hospital surgical practice presented themselves for treatment, comparatively late with relatively advanced malignant growths and a large percentage showing metastatic involvement. Only 2 patients are known to be alive more than five years later. The mortality rate was 92 per cent.

Of the other group of 35 patients seen in dermatologic practice 17, or 48.6 per cent, survived from seven to eighteen years. As a group these patients were seen comparatively early in their disease and the great

majority were free of metastatic dissemination when they were first treated.

The results obtained indicate that the only hope of reducing the high mortality rate in cutaneous melanoma lies in early diagnosis and thorough destruction of the primary lesion before dissemination takes place, either by electrocauterization (not electrolysis) or by radical scalpel excision.

Experienced clinical judgment is necessary in deciding in what cases dissection of regional lymph nodes should be done. If the lymph nodes are clinically involved the chances of cure by any therapeutic method are practically nil. Melanomas on the fingers, hands, arms, feet and legs should be treated by amputation followed by surgical dissection of the regional lymph nodes in every case.

The complete scalpel excision or thorough destruction of flat, nonhairy pigmented nevi (junction type nevi) from areas subject to chronic irritation such as the face, ears, extremities and particularly the feet is the best form of prophylaxis for cutaneous melanomas.

Euclid at Fourteenth Street

ABSTRACT OF DISCUSSION

DR H. FORD ANDERSON, Washington, D. C. The handling of melanomalignancy is one of the most serious problems that faces the dermatologist, who by training is best adapted to meet the problem from the diagnostic angle. The differential diagnosis and classification of pigmented lesions is practically a daily chore for all of us. Publications by men of other groups are on record in which seborrheic keratoses and keratomas easily identified from both their photographs and biopsies are included under the heading of melanotic tumors. From the standpoint of nomenclature to me the word melanoma from its literal translation means merely a tumor containing melanin and may be either benign or malignant. The authors clearly state here that when they use the term melanoma they mean melanomalignancy and thereby avoid any confusion as to site of origin which would be of no practical value in this type of discussion of the problem. Many other physicians have also developed skill in the diagnosis and treatment of melanotic tumors. This is particularly true of the better plastic surgeons. The time was when surgeons would criticize the dermatologist when the opportunity arose and, when a recurrent melanotic malignant growth came into the dermatologic clinic after surgery had been performed on the original lesion, students were told about the inadequacy of surgery and that if the blood vessels and lymphatics had been sealed by electrical methods this calamity would not have happened. In both instances both men were wrong. Provided that in both instances there was no recurrence at the site of the previous lesion which always is the best criterion of adequate therapy. All this was wrong. There are men in both fields capable of handling any possible situation that has not already advanced beyond the point of all hope and today most of the better men in both fields recognize this fact. Unfortunately this point of all hope in melanotic malignant growths often comes early and insidiously. The prophylaxis in removal of premalignant lesions especially those subject to irritation whether by sun, by clothing or by electrolysis is again properly emphasized as well as the type of lesion most apt to cause trouble. The next most important problem is recognition and treatment of the malignant lesion, which can be summed up as total destruction and must be adequate. Adequacy can be obtained by surgery, electrical destruction or combinations of these. The importance of the biopsy cannot be overemphasized. Without it adequate therapy and prognosis would be impossible in many instances.

DR EUGENE F. TRAUB, New York (Flushing, N. Y.) In the case of melanomas I believe our only hope of reducing the mortality rate is through prophylactic treatment. Fortunately while pigmented nevi and pigmented marks on the skin of

various types are common, the development of melanoma is exceedingly rare. The disease has such a bad reputation solely because when malignant melanoma has actually developed the prognosis has always been exceedingly poor. For this reason I have attempted to tackle the problem by trying to get a line in the type of pigmented mark which is liable to become a malignant melanoma, the idea being that once we have ascertained correctly what types of pigmented marks are dangerous we can then intelligently discuss the feasibility of their prophylactic removal. Since it is of the greatest importance to learn as much as possible about the type of lesion from which malignant melanomas arise, I suggest that extreme care be taken in describing the exact type of lesion from which this has apparently occurred when reporting such cases. The exact duration of the original mark, prior to the time malignant change apparently occurred, is also valuable information to record. With regard to the matter of biopsy for diagnostic purposes, most pigmented lesions in which the question of malignant melanoma arises are fortunately usually small. While not particularly opposed to the diagnostic biopsy, I believe it is far better to excise the entire lesion completely and submit it for study than first to remove a small portion, which might give false information and which usually must be followed by a complete excision within a short space of time in any event. Where the marks are extremely large, which is rare, of course this might not apply. Concerning the diagnosis of malignant melanoma, in late cases this presents relatively little if any difficulty, but in early lesions great differences of opinion may arise, both clinically and, I believe particularly, histopathologically. I have frequently found that the best skin pathologists will differ widely in their opinions as to the innocence or the malignancy of a lesion on examination of microscopic sections. It becomes imperative to balance such opinions carefully against the clinical appearance of the lesion and its course or development while under observation. The most important part of this entire subject is the earliest destruction of those lesions which might be looked on as dangerous.

DR LOUIS A. BRUNSTING, Rochester, Minn. There is no treatment other than excision for melanomas. If the patient is elderly, operative measures may be postponed unless the lesion is at a site which is subject to irritation. Not all melanomas are pigmented nor, on the contrary, are all pigmented lesions melanomas. It is desirable to have microscopic examination of all suggestive lesions. Those who advise conservative treatment and who do not have microscopic examinations of tissue to back up their findings may include such lesions as foreign body reactions, deposits of hemosiderin, verruca senile or blue nevus. Once melanomas show signs of growth or ulceration, the outlook is grave regardless of the type of treatment. Even though the lesion is excised widely it is doubtful whether the use of x-rays or radium is of additional benefit, and such procedures as amputation of the extremities or even excision of the regional lymph nodes are probably useless.

DR S. W. BECKER, Chicago. On the basis of studies of pigmentation, starting with normal pigmentation and extending to the nonmalignant and to the malignant conditions, I have gained certain ideas which I believe will withstand scientific scrutiny. In what clinical work I have had the opportunity to carry out, certainly these have been borne out. In the first place melanomas do not metastasize early. That idea has been gained because the melanoma has not been appreciated at the earliest stage. One patient whose picture the authors presented had a brown lesion appearing five years previously. In my opinion that brown lesion at the time of appearance was a lentigo maligna, which is not a nevus but is already a malignant melanoma, and I do not believe that a melanoma arises from nevi as often as it does from the so-called lentigo maligna. The junction type nevus is a sort of misnomer. Some lesions which have been presented as junction type nevi are already lentigo maligna. These malignant changes can be readily appreciated by the fact that groups of cells are working their way through to the cutaneous surface. In ordinary nevus, a flat nevus, such as the one Dr Traub presented, the patient with the thigh and leg covered with nevi, you may find almost the same picture. You will find groups of nevus cells all attached to the epidermis,

but you do not find them working their way through the epidermis to the cutaneous surface. If melanoma does arrive from a nevus, it is the smooth brown type and not the blue black variety. Patients admit that the lesion when it started was brown and over a period of many years it changed and became darker in color and blue black, and at that time it was already a malignant melanoma and not a nevus. Malignant melanomas arise at the junction of the epidermis and dermis, and, if you are confronted with a quiescent nevus, all that you have to do is to destroy enough of the lesion to destroy melanoblasts at the junction. You do not have to worry about the nevus cells deeper down. The first thing, of course, is to be sure of the diagnosis. The early recognition, of course, is extremely important. Any brown lesion which has appeared recently and is enlarging, and any preexisting brown lesion which is enlarging or becoming darker, should be submitted to biopsy to eliminate lentigo maligna. Pathologists and even dermatologists have a great deal of difficulty with the diagnosis of doubtful cases.

DR ALFRED HOLLANDER, Springfield, Mass. The authors have given us an instructive paper on melanomas. If we are dealing with the common cutaneous melanomas we have nothing to add. There is another angle to this problem, however. We see frequently nonpigmented tumors, especially warts located on the scalp. When we see those lesions we should be careful in regard to the treatment. I should say that not too rarely when we do a biopsy on those tumors we see a melanotic stage developed within the tumor which cannot be seen clinically. I should recommend that in all these tumors, especially when they have a tendency to be injured by mechanical friction, you do a biopsy and find out whether or not there is already a so-called nonpigmented melanoma. Regarding therapy, I have done electrocutting for the last eleven years, and I should say that if we are able to remove the tumor with the scalpel we should do that, because I have never seen wounds set by the electrocutting method heal as nicely and as quickly as they will when removed by the scalpel.

DR FRANCIS A. ELLIS, Baltimore. The question of melanomas provokes discussion because they are one of the common dermatologic lesions and occasionally they are either clinically or histologically malignant. According to several standard text books and dictionaries, a melanoma is a tumor composed of cells which form melanin pigment (melanoblasts), and they may be either benign or malignant. The classification of these tumors may be difficult with patients below the age of puberty. Recently I was consulted by several surgeons concerning melanomas of the face removed from 2 patients, 1 a child 1 year and a half old and the other a boy 10 years old. Both of the growths were smooth and brown. Microscopically they showed clear cells in the junction between the basal layer and the cutis, but there were nevus cells penetrating deeply into the cutis without forming nests. From the microscopic appearance they were malignant. Until some one can advance some better diagnostic criteria, one will have to wait and see what happens. It is my opinion that many of these melanomas in infants and children are frequently histologically malignant but are usually clinically benign. The tumors are in the formative stage and therefore show the malignant histologic picture.

DR JAMES R. DRIVER, Cleveland. I thank the discussers for their valuable remarks. The prognosis of melanoma is not so bad as is generally supposed if one keeps in mind the importance of its early diagnosis and adequate treatment. The removal of suggestive pigmented lesions from areas likely to be subjected to chronic irritation is the best type of cancer prophylaxis.

Early Work on Coronary Disease—To the English physicians must be given the credit for the earliest productive work on the coronary artery in its relation to angina pectoris. Heberden was the pioneer clinician of angina. Jenner and Parry, by necropsy and logical reasoning, showed the relation of the syndrome to disease of the coronary artery. Allan Burns was the first to try to prove the correctness of the myocardial ischemia theory by a purposeful planned experiment—Herrick, James B. A Short History of Cardiology, Springfield, Ill., Charles C. Thomas, 1942.

Clinical Notes, Suggestions and New Instruments

ALLERGY TO ARGYROL

LEO H. CRIEP, M.D. PITTSBURGH

A case of acquired allergy to argyrol¹ is reported because it is an instance of sensitivity which must be a great deal more common than is recognized and because it offers an opportunity for the study of the possible mechanism involved in drug allergy.

A thorough search of the medical literature fails to reveal more than a single reported instance of allergy to argyrol.² In the one referred to a young woman received nasal treatments with argyrol for several years twice a week for a suppurative sinusitis. From the description given, it is also likely that she had some allergic nasal manifestations. The treatments were discontinued for several months and on being resumed the patient had an immediate reaction. This consisted of massive swellings of the face, generalized urticaria and symptoms of collapse. On several occasions subsequent treatments evoked similar, severe, immediate reactions. Scratch tests with 10 per cent argyrol were positive.

REPORT OF CASE

M. S., a man aged 26, has had seasonal hay fever for four years. Asthmatic breathing first developed at the end of the 1941 hay fever season. It further appears that the ingestion of even a very small quantity of milk gives rise to violent cramps and diarrhea. He presents evidence of considerable infection in the paranasal sinuses. Considerable sneezing, nasal blockage, rhinorrhea and even wheezing would develop during the course of local treatments with the drug, necessitating the administration of epinephrine on one occasion. Some time later severe asthma followed spraying of the throat with argyrol for pharyngitis. It finally became obvious that the patient's discomfort was more than that usually experienced from the mechanical irritation of the nasal tampons, hence local treatments with argyrol were discontinued.

Scratch (skin) tests performed with a weak (1 per cent) solution of argyrol produced a definite local reaction while a control test with the drug on another person was negative. Similarly, an intradermal test with a 1 per cent argyrol solution yielded a very severe local and a mild constitutional reaction. The ophthalmic test was positive with argyrol. Controls were uniformly negative.

As an aid in determining the specificity of these reactions, passive transfer tests were done. One-tenth cc of the patient's serum was injected intradermally into the arm of a normal person and twenty-four hours later 0.05 cc of 1 per cent solution of argyrol was injected into the sensitized site. A definite local reaction resulted, indicating the presence in the patient's serum of specific antibodies (reagents) against argyrol. Controls were negative. It would therefore appear that the patient is specifically sensitive to argyrol—first because of the presence of demonstrable antibodies (reagents) in his serum and second because of the development of a constitutional reaction on exposure.

COMMENT

This instance of allergy to argyrol is of interest because unlike most instances of drug allergy it is associated with demonstrable specific antibodies. There are persons who as a result of sensitivity to drugs such as acetylsalicylic acid may have a severe and even a fatal attack of asthma following the ingestion of even small doses of the drug. However, because of the nonprotein nature of the drug specific anti-

bodies are not demonstrable in the serum of such patients. Skin testing to acetylsalicylic acid and similar drugs is usually not of any value. It is thought that in these instances the allergy is to a combined protein, a combination of the drug with protein body molecules. My patient did not have any cutaneous reactions to solutions of silver nitrate. It is obvious then, that the allergy must be either to the protein vehicle of argyrol or to the combination of argyrol with this protein vehicle. In contrast to the type of allergy to acetylsalicylic acid, positive reactions were obtained in this case to colloidal protein solutions of the drug.

According to the Council on Pharmacy and Chemistry of the American Medical Association³ argyrol is a silver preparation consisting of a colloidal solution of silver or silver oxide in alkali-proteins. I was interested in determining the nature of the protein vehicle of argyrol in order to test the patient's sensitivity to this protein alone as well as to argyrol. Repeated attempts to obtain either this information or the protein vehicle itself for separate testing were unsuccessful. The A. C. Barnes Company,⁴ proprietors of argyrol, refused to cooperate in this investigation, claiming that 'to furnish the solution without the silver would be impractical because it would deteriorate and become mildewed'.¹ Nor is the nature of this protein known to the Food and Drug Administration⁵ or to the Council on Pharmacy and Chemistry. According to the U. S. Dispensatory argyrol "is said to be a combination of silver with a protein produced by the electrolysis of serum albumin, while one synonym given for argyrol by this source is 'silver vitellin,' and vitellin is a commercial variety of lecithin derived from eggs.

There are various essentially similar colloidal silver preparations on the market. They are all grouped in the U. S. Pharmacopeia under the common name of 'mild protein silver'. The protein vehicle in some of these such as solargentum (Squibb), is known to be gelatin. Formerly argyrol was included in New and Nonofficial Remedies in 1928. It was omitted³ because of 'unsubstantiated and misleading statements in regard to its therapeutic actions and chemical individuality' and because of a disregard of the pharmacopeial title.

The A. C. Barnes Company throughout the controversy which led to the omission of argyrol from N. N. R. consistently maintained that its product was different in composition from that of other products included under the 'mild protein silver' in the U. S. Pharmacopeia. In 1928 the American Medical Association Chemical Laboratory reporting on argyrol for the Council on Pharmacy and Chemistry stated 'In our opinion tests do not indicate that argyrol is essentially different from the other preparations in reference to the therapeutic component, i. e. the concentration of silver ions as indicated by the yeast test. On the other hand, according to the Council on Pharmacy and Chemistry, the yeast test showed that argyrol agrees with the other preparations of mild protein silver in the proportion of its ionized silver.

In view of this information the patient was tested intradermally with similar dilutions of Solargentum (Squibb) and Heyden's U. S. P. mild protein silver. Negative cutaneous reactions and negative passive transfer tests were obtained with both of these products indicating that the protein vehicle must be different. Local nasal tampons with both of these preparations failed to give rise to local symptoms or asthma.

It would appear that in both instances referred to this allergy occurred in otherwise allergic persons who acquired a sensitivity to argyrol following sufficient exposure to this substance. There is still another interesting feature to both of these instances, namely that the constitutional reaction occurred following resumption of treatment with argyrol after the patient

From the Department of Allergy, University of Pittsburgh School of Medicine and the Allergy Clinic, Montefiore Hospital.

had discontinued this therapy for a few months. This is in accord with my own experience in cases of acquired allergy to biologic products such as liver extract and pancreatic extract.⁶ These allergic patients seem to develop constitutional reactions, usually after they have taken repeated treatments, then discontinued treatments for a while and finally resumed them. The reaction occurs as a rule after the first of the last series of such treatments.

One wonders whether the supposed rarity of the occurrence of allergy to argyrol in nose and throat practice may not be due to a failure to recognize its presence. Patients receiving such treatments frequently protest about the discomfort it causes them, and in many instances it is not easy to recognize this discomfort as an allergic manifestation because the primary symptoms from which the patient seeks relief are so similar to those which develop coincident to treatment. In other instances the reaction may be too mild to be recognized. It is therefore thought likely that rhinologists who suspect a possible allergic reaction following the use of argyrol may do well to change to some other mild protein silver preparation and avoid these allergic reactions without depriving the patient of the desired therapeutic effect. It is generally agreed that the therapeutic effect of all mild protein silver preparations is about the same. In view of this, it may be advisable to change from one preparation to another at stated intervals in the treatment of patients who receive regularly local applications of such preparations and thus avoid the development of allergic manifestations.

Several workers⁷ noticed the occurrence of anaphylactic shock in guinea pigs and rabbits exposed on successive injections with collargol (a colloidal silver preparation) during the course of animal experimentation. Undoubtedly this shock was due to anaphylactic sensitization to the protein vehicle in collargol, which is a product of mild protein silver similar to argyrol.

CONTACT DERMATITIS FROM RUBBER SERVICE MASK

CAPTAIN IRVING A LEWE
MEDICAL CORPS ARMY OF THE UNITED STATES

Rubber respirator dermatitis has been brought to the attention of the medical profession by a recent report of 16 cases observed at one of the Royal Navy depots by Petro.¹ The following case is reported because I have found no reference of respirator dermatitis in the United States military service.

REPORT OF CASE

W H V, a white soldier aged 42, admitted to the Station Hospital, Camp Roberts, California, Sept 1, 1942, complained of an itching cutaneous eruption on the face of less than twenty-four hours' duration.

The patient stated that on August 26 he had gone through the gas chamber for the first time, wearing his service mask which was brand new. A few hours later an itching cutaneous rash developed on the face which persisted until the following day. The mask was worn again for five minutes at a gas drill on August 31. Three hours later a similar eruption of greater severity appeared. He was hospitalized the following morning.

1 Petro John. Respirator Dermatitis. *Brit M J* **1** 631 (May 23) 1942.

A review of his past history revealed that he had had eruptions on the scalp, both axillae and crural regions on and off since puberty, the eruption would be mild and relatively asymptomatic. There was a history of contact dermatitis from leather watch bands and from an elastic abdominal binder worn after an appendectomy many years before. The family history was negative for allergy.

On admission, the patient presented a bright red erythematous vesicular cutaneous eruption confined to the peripheral portion of the face corresponding to the area in close contact with the gas mask. The central portion of the face was spared, giving the appearance of an oval band of dermatitis. There was a coincidental mild chronic seborrheic dermatitis of the scalp, axillae and crural regions. No other physical abnormalities were found. A blood count was normal and urinalysis was negative.

The facial dermatitis was treated with Burow's solution compresses and calamine lotion, resulting in complete clearing of the eruption in one week. The seborrheic dermatitis responded to treatment with a sulfur-resorcinol lotion.

September 9 the patient was allowed to wear his gas mask in the ward for ten minutes. Three hours later he was aware of itching at the site of contact with the mask. Within an hour this was followed by an erythematovesicular cutaneous eruption which became progressively more severe. This time there was pronounced edema of the eyelids. When seen the following morning the eyelids were reddened and swollen shut, and there was a greatly edematous erythematovesicular cutaneous eruption of the periphery of the face most severe on the forehead and frontal scalp, here there was considerable oozing and crusting. By the next day the edema was even more pronounced with boggy tissue of all the loose tissue under the chin, and itching was intense.

The eruption gradually subsided with compressing and application of bland antipruritic lotions and ointments. Patch tests were placed on the patient's back on September 21, a sample of unprocessed rubber and small samples of rubber from the three service masks in current use at Camp Roberts being used. The patches were removed in forty-eight hours. A positive reaction was elicited with the samples from service mask M2-A1, the type that the patient had been wearing, and service mask M-3, a diaphragm mask made of the same type of rubber.

The tests with unprocessed rubber and service mask M1-A2 were negative. The positive reactions were manifested by erythema and small papules and vesicles confined to the site of the patch test. Another reading taken at seventy-two hours showed a much more pronounced reaction of the positive tests with slight peripheral spread.

By September 26 the dermatitis had entirely subsided and the patient was permitted to wear mask M1-A2 in the ward for ten minutes. No reaction resulted. This test was repeated in the ward the following day for twenty minutes without reaction. The patient was discharged from the hospital on September 28 and provisions were made for him to exchange his mask for one of the M1-A2 type.

COMMENT

It is interesting to note that the face pieces on the two masks to which the patient demonstrated sensitivity were made of the same type of rubber. His present mask is of an older type, the rubber of which is processed in a different manner. This is in accordance with previous reports² in which it has been shown that most cases of rubber dermatitis are due not to the rubber itself but to the antioxidants and accelerators used in the manufacturing process. No attempt was made to determine the offending substance in this case. If further cases are found it would be wise to investigate the manufacturing processes.

HANDBOOK OF NUTRITION VIII

IODINE IN NUTRITION

GEORGE M. CURTIS, PH.D., M.D.

AND

MILDRED B. FERTMAN, A.B., M.A.

COLUMBUS, OHIO

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed

In the struggle for survival in this world conflict, in which both physical and emotional demands on the body's resources are rapidly mounting, the problems of nutrition assume an even greater significance. And thus iodine, a nutritional necessity, essential in the normal regulation of the energy output of the human body comes to take its place in any all inclusive war effort.

DISTRIBUTION OF IODINE AND GOITER

Iodine is widely distributed throughout all nature. It occurs in many forms, both organic and inorganic. It is found in nearly all living things as well as in the air, water, soil and rocks. Not the sea, as is popularly believed, but the earth's crust is the major storehouse of iodine.¹

Iodine is not uniformly distributed but varies with the local geologic conditions of the soil and water. Inversely related to the distribution of iodine is the incidence of endemic goiter. The highest incidence of goiter is found among the Alps, Pyrenees and Himalayas, the Thames Valley in England, certain inhabited districts of New Zealand, the region of the Great Lakes and the Pacific Northwest.²

Throughout the United States there are similarly varying degrees of iodine deficiency. A low occurrence of iodine together with a high incidence of goiter are especially prominent in the Central Plain of North America, in contrast to the low incidence of goiter on the sea coasts, where large amounts of high iodine containing sea foods are consumed. On the other hand, the district of Salt Lake City has a high incidence of goiter even though the water of Great Salt Lake has a higher iodine concentration than the ocean. However, neither vegetation nor fish for human consumption comes from the nearly lifeless waters of the Great Salt Lake.³

The incidence of goiter can be correlated with the iodine intake of a given region. This in turn is largely dependent on the soil iodine. Intake iodine is derived essentially from the food and to a lesser degree from unsupplemented salt or from water.⁴ About 14 micrograms daily was formerly said to represent the difference in iodine intake between goitrous and nongoitrous

regions.⁴ However the estimation of regional differences in iodine consumption becomes less pronounced as the interstate transportation of foods, drinks, vegetables, fruits and fertilizers increases.

The amount of iodine in the local drinking water may be regarded as a measure of the iodine content of the soil and, consequently, of the fruits, grains, grasses and vegetables grown in the region. It is not, however, important as a source of nutritional iodine save in unusual circumstances.⁵ McClendon has divided the United States into sections according to the iodine content of the waters. In a section extending from Oregon to the western part of Maine and in another from Nevada to the western part of Virginia the water iodine is low and the incidence of goiter high.² The Michigan studies revealed that the incidence of goiter in a given locality is inversely proportional to the amount of iodine found in its waters.⁶

The food iodine is the most important factor determining the goiter incidence in a given region. Japan presents an outstanding example of a goiter free area. Yet Formosa, which like Japan is geologically low in iodine, has a high incidence of goiter. The absence of goiter in Japan is a consequence of the extensive importation and consumption of seaweed which is rich in iodine.²

In South Carolina, where the incidence of goiter is low, the amount of iodine in the vegetables is considerably higher than in the more goitrous Northern and Western states.⁴ Yet the cotton and tobacco growing South as a whole comprising a great part of the goiter free United States⁷ fails to produce sufficient food and feed crops for its own needs.⁸ Thus, most of the canned foods and other food products in the United States come from sections of the country poor in iodine.⁹

The regional incidence of goiter is also correlated with the milk iodine of the area.⁹ This follows since the iodine content of the soil and vegetation determines the iodine intake of the lactating mammal.¹⁰ Consequently, the milk iodine depends on the soil of the locality from which it is obtained, provided supplemental iodine is not being consumed.¹¹ This is also true of eggs and other food products.¹

In the Chinese province of Yunnan there is a high incidence of goiter and considerable cretinism. Men and women working on the Burma Road show an incidence of thyroid enlargement as high as 80 per cent with an average well over 50 per cent. Residence in a Yunnan goitrous district for six months appears sufficient to produce thyroid enlargement in susceptible individuals. Iodine deficiency in the provincial salt and vegetation appears responsible. As the result of military occupation by the Japanese, the hinterland of China is now cut off from its former coastal supply of

high iodine-containing salt. Consequently large areas of free China must now depend on Yunnan salt, which is deficient in iodine.¹³

IODINE AND THE NORMAL THYROID GLAND

The human thyroid gland is a principal storehouse for iodine. Weighing ordinarily about 25 Gm and containing about 10 mg of iodine, it normally maintains an iodine concentration of around 40 mg per hundred grams. It was shown long ago by Marine and Lenhart that, when this concentration falls below 10 mg per hundred grams, hyperplasia ensues and goiter may consequently develop.¹⁴

No other organ of the body has the power of iodine concentration possessed by the thyroid gland. The whole blood iodine averages less than 1 part in 25 million while the thyroid gland normally contains approximately 1 part in 25 hundred. This indicates that the thyroid gland can concentrate the iodine it obtains from the blood by a factor of at least 10,000.

Within the colloid in the alveoli of the thyroid gland iodine is stored in the form of the amino acids diiodotyrosine and thyroxine containing respectively 59 and 65 per cent iodine. King suggests that the thyroid hormone has undergone a process of evolutionary development in complexity, from a simpler physiologically active iodine compound produced in the tissues.¹⁵

The accepted facts of thyroid physiology indicate that iodine is selectively absorbed by the active thyroid gland. Furthermore in some measure the glandular function is regulated by its iodine content. Studies with radioactive iodine have shown that iodine is quickly brought to the gland by the blood stream and rapidly converted by the thyroid cells into organic compounds, moreover, that within a matter of a few hours these organic iodine compounds may return to the circulation.¹⁶

The total thyroid iodine content varies directly with the weight of the gland, while the relative iodine content is inversely proportional to its weight.¹⁵ This inverse relationship between the size of the thyroid and its iodine concentration was noted as early as 1896 by Baumann¹⁷ and was later confirmed by Marine and Lenhart in 1909.¹⁴ The thyroid iodine content varies inversely with the incidence of nodule formation, the percentage of epithelial proliferation, the height of the follicular epithelium, the incidence of lymphocytic infiltration and the occurrence of degenerative changes.¹⁸

Iodine intake is the principal factor which determines the iodine content of the thyroid and overshadows other differences due to species, age or sex. Small differences in the supply of iodine are reflected in the iodine content of the gland. The thyroid fixes a relatively higher

percentage of iodine from smaller doses of administered iodine than from larger.¹⁸

Since iodine intake is so largely dependent on the soil and consequently on plant iodine, the gland concentration varies with the geographic distribution of iodine. Thus, in nongoitrous Texas the fat free thyroid contains 6 mg of iodine per gram, whereas in goitrous North Dakota it contains only 3.2 mg per gram.¹⁹

King found the total thyroid iodine higher from May through October than from November through April, although the gland concentration remained fairly constant.¹ The iodine content of the ruminant thyroid was found to be maximum in late summer and early fall and at a minimum in winter and early spring.⁶ This variation in thyroid iodine may be attributed to fluctuation in the amount of iodine available from the pastures.¹ Perhaps more fundamental than the seasonal per se is variation in the foodstuffs available during each season.² Orr and Leitch analyzed various plants grown in Scottish pastures and collected during different months of the grazing seasons. They demonstrated an increase in the autumn iodine content.⁷

Age as well as sex differences in thyroid iodine have also been reported.³

IODINE AND THE PATHOLOGIC THYROID GLAND

Endemic goiter and its sequelae are fundamentally a result of iodine deficiency.² The ultimate cause of endemic goiter however is not clear. The immediate cause is a deficiency of iodine necessary in the production of the high iodine containing thyroid hormone. This deficiency may be absolute as in areas of subnormal iodine intake, or it may be relative, subsequent to various demands on the body which increase the needs for thyroid secretion.²⁴ Such factors include puberty, pregnancy, lactation, the incidence of infectious diseases, ingestion of toxic substances and high calcium intake, as well as those conditions which interfere with the gastrointestinal absorption of iodine.

The microscopic changes in the thyroid closely parallel the chemical findings.¹ Brumann and Roos⁵ and also Oswald¹⁸ were the first to observe that, if iodine is withheld compensatory hypertrophy of the thyroid occurs. They noted that the iodine content of the thyroid is proportional to the amount of colloid present and that in colloid goiter the concentration of iodine is definitely below that found in the normal gland.

When normal or goitrous thyroid glands obtained from goitrous regions are compared with other normal

or goitrous glands, it is found that the glands from the goitrous regions are the largest and have the highest incidence of nodule formation, the smallest follicular size and the lowest iodine content¹⁵

If iodine is administered to a person with a normal thyroid gland or with a colloid goiter there is a subsequent increase in the iodine content of the gland, with no notable change in its structure and with no hyperplasia of the remaining lobe after single lobectomy. If iodine is withheld, however, the iodine content of the gland gradually decreases, and hyperplasia will ensue if one lobe is removed¹⁴

Remington and his associates have shown that it is possible to produce enlarged and hyperplastic thyroid glands in young rats fed for five weeks on a diet extremely low in iodine²⁷. The addition of iodide to the diet prevented the development of goiter, nevertheless, increased iodine intake by newborn rats during the first four weeks of life did not permit sufficient storage of iodine to prevent the development of goiter when iodine was later withdrawn. Varying the calcium content of the ration or its calcium-phosphorus ratio or the presence or absence of vitamin D did not significantly affect the degree of goiter produced²⁷

The blood iodine is increased during pregnancy²⁸. There is also an increased loss of iodine in the urine²⁹. Thyroid hyperplasia may be demonstrated in from 70 to 80 per cent of the patients²⁴ and may also occur during lactation, since considerable iodine is lost in the milk²⁴. It has been noted that feeding iodine to pregnant animals prevents microscopic pathologic changes in the thyroid³⁰

IODINE AND THE EXTRATHYROID TISSUES

The total iodine content of the human body is variable and depends on divers factors. A normal man weighing 70 Kg may be estimated reasonably to contain about 50 mg of iodine, which is equivalent to about 1 part in 1,400,000 of body substance. Iodine thus forms less than 0.00008 of 1 per cent of the body weight. Every cell in the body is said to contain some iodine,³¹ however, of the total body iodine, about one half can be assigned to the muscles, one fifth to the thyroid, one tenth to the skin and one seventeenth to the bones³²

Several investigators maintain that the iodine concentration of the endocrine glands, exclusive of the thyroid and parathyroids, exceeds that of the nonendocrine tissues³³. King, investigating mammalian tissue iodine,¹⁵ and Libecap, determining the iodine content of normal

human tissues,³⁴ were unable to confirm this relatively high iodine content attributed to the nonthyroid endocrines. Moreover, they both found that the iodine content of the pituitary as well as of the central nervous system, was unusually low.

The importance of the liver in the physiology of iodine is emphasized by Elmer³⁵. This is further supported by the consistently high iodine content found in the bile³⁵. With the exception of the thyroid gland and the hair, bile contains the highest iodine concentration in the human body³⁴

Von Fellenberg found that the lungs retain more injected iodine than other organs, however they may also lose it more rapidly. Since the administration of iodide did not increase the amount of iodine in the expired air, he concluded that the lungs lose iodine in some other manner³⁶. Ariel and his co-workers³ and Lein,³⁸ independently using radioactive iodine found that next to the thyroid gland the lungs collect most of the iodine injected. Lein was unable to correlate the large quantity of iodine held in the lungs with the iodine expired in the air.

IODINE AND THE BODY FLUIDS

Human blood normally contains a fairly constant concentration of iodine. Fractionation studies reveal that about a fourth of this appears to form part of the circulating thyroid hormone³⁹. The other three fourths, consequently, would represent the iodine of nutrition together with products of the breakdown of the high iodine containing thyroid hormone.

Various values, ranging from 3 to 20 micrograms per hundred cubic centimeters, have been ascribed by different investigators to the normal blood iodine level⁴⁰. These vary with the method of iodine determination, the geographic area and divers other factors. The average blood iodine of 29 normal individuals in central Ohio was found to be 4.2 plus or minus 1.2 micrograms per hundred cubic centimeters²⁸. The blood iodine is significantly increased during pregnancy, during parturition, in unmedicated toxic nodular as well as in exophthalmic goiter (chart 3) and in certain non-thyroid diseases⁴¹. The higher blood iodine observed in certain patients with treated toxic nodular or with exophthalmic goiter may be due to the iodine medication of these patients,⁴² since the administration of iodine in all forms thus investigated increases the circulating blood iodine⁴³ (chart 1).

In hypothyroidism the average total blood iodine does not differ as significantly as might be expected

from the normal²⁸ However, the acetone insoluble fraction, which presumably contains the circulating thyroid hormone, has an average value of about one-half normal and a range which barely overlaps the lower normal²⁹

Blood iodine levels vary, as does the concentration of the thyroid iodine, however, the range is narrower²⁴ Some find a variation of the blood iodine with age,⁴⁴ others maintain that there is a seasonal variation,⁴⁵ while some note sex differences in the blood iodine level⁴⁶ We were unable to substantiate either a significant sex difference or any seasonal difference in a study of hundreds of patients with various diseases²⁸

Chart 1—A thirty day iodine balance of a normal person (J R a man aged 56 Oct 10 Nov 13 1936) On the original low iodine intake the balance is negative and the principal iodine loss is in the urine Iodine storage occurs after giving milk with an increased iodine content obtained from a dairy herd receiving supplemental iodine and further increases when small amounts of iodine are administered daily Note the consequent rise in the blood iodine Reproduced from a chart that appeared originally in the *Annals of Surgery* October 1938 p 579

In certain diseases the blood iodine varies independently of the basal metabolic rate, in others the two are similarly affected We have found the blood iodine significantly correlated with the basal metabolic rate in 70 patients with toxic diffuse goiter, in 29 with toxic nodular goiter and in 80 with nontoxic nodular

goiter²⁸ (chart 3) Mobius and Nolte have noted correlation between the basal metabolic rate and increased blood iodine⁴⁷

Thyroidectomy, either for thyroid disease or experimentally, exerts an important effect on the blood iodine Immediately following total thyroidectomy there ensues a transient increase in the blood iodine, which persists for about thirty-six hours After varying periods following total thyroidectomy the blood iodine decreases to about one-third normal⁴⁸

Under maintained basal conditions the normal adult excretes a surprisingly constant amount of iodine in the urine⁴⁹ (chart 1) The urinary iodine varies geographically It is higher in sea coast regions than in those inland²⁴ and is higher in nongoitrous than in goitrous regions In five nongoitrous regions from 72 to 343 micrograms a day, averaging 165 micrograms, was excreted, in contrast to a range of from 27 to 64 a day, averaging 42 micrograms, in five goitrous regions⁴⁹ The average amount of urinary iodine excreted during twenty-four hours by normal adults in central Ohio, a moderately goitrous region, is 51 micrograms⁵⁰

Several factors increase the loss of iodine in the urine, such as hyperthyroidism⁵¹ (chart 3), menstruation,⁵² pregnancy,²⁹ surgery⁵³ and the administration of iodine in nearly all forms⁵⁴ (chart 1) Milk with an increased iodine content, obtained from dairy herds fed supplemental iodine and given to patients with varying types of thyroid disease as well as to other hospital patients, consistently increased the urinary output of iodine The patients were thus maintained in a positive iodine balance⁵⁵ (chart 1) On the other hand, fasting decreases the urinary excretion of iodine⁵⁵ (chart 2) However, the decrease is less if the fasting is preceded by an iodine rich diet⁵⁶

Iodine has been demonstrated in lymph,⁵⁷ cerebrospinal fluid,⁵⁸ perspiration⁵⁹ (chart 3), chyle, ascitic fluid pleural exudates and milk In milk it plays an important role in supplying needed iodine to the growing infant with a resultant depletion of the mother¹⁰ If iodine feeding is essential to health, it is even more

iodine reserve or by an increased intake. Otherwise iodine deficiency goiter may develop.⁶⁰ Administration of iodine to animals increases the milk iodine.⁶¹

GOITER PROPHYLAXIS BY IODINE

'The results of iodine treatment of goiter have been so successful and so well recognized by the lay public that they constitute a chapter unique in the history of nutrition.'⁶²

Fortunate was the empiricism which led the ancients to use burnt sponge or seaweed in the treatment of goiter. Iodine was then unknown. It was not until the year 1811 that iodine was accidentally discovered by Courtois as a by-product resulting from the use of seaweed in preparing war materials for Napoleon. Within a few years Sir Humphry Davy had isolated iodine from sponges, seaweed and other forms of marine life. Thence followed a fruitful century of clinical investigation extending from Straub of Berne to Plummer of Rochester, and of fundamental experimental researches dating from Boussingault of Paris through Chatin, Baumann, Kendall, Marine, von Fellenberg and others to Harington of London.

Today iodine prophylaxis against goiter is most widely recognized, while iodized salt is used throughout the entire United States, even on Nantucket Island and in the Philippines.⁶³ The extensive and increasing popularity of the use of iodized salt obtained an original impetus from the experiments of Marine and his co-workers in Akron, Ohio.

Marine's significant studies on the prevention of goiter were made on a large group of schoolgirls. Approximately one half voluntarily received sodium iodide daily in a 0.2 Gm. dose distributed over a period of two weeks each spring and fall. The results of two and one-half years of observation showed that of the girls who had no goiter at the beginning of the test 0.2 per cent of the 2,190 receiving iodine developed enlarged thyroid glands, while 21.5 per cent of the 2,305 who did not receive supplemental iodine developed goiter. Of the girls with an initial thyroid enlargement 65.4 per cent of 1,182 who received iodine showed a reduction in the size of the thyroid gland at the end of the year, in contrast to the 13.8 per cent of the untreated 1,048 who showed some diminution in the size of the goiter.⁶⁴ In this same study Marine and Kimball point out that goiter is most apt to develop during tetraline puberty or pregnancy.

The character and results of the Ohio demonstration stimulated other similar efforts throughout the world, particularly in Switzerland, Austria and Germany. Iodine prophylaxis in Switzerland brought with it the steady decline year by year of cretinism, such an important economic factor to the Swiss. The institution of iodized salt in the canton of Appenzell in 1922 reduced enlarged thyroid glands in newborn infants from an

Chart 3—A comparison of the average iodine balance of three normal persons with that of 4 patients with nodular goiter and 3 with exophthalmic goiter. All were maintained on a low iodine intake. Reproduced from a chart that appeared originally in the *Journal of Clinical Investigation*, November 1938, p. 734.

incidence of 50 per cent to almost nothing. The consumption of iodized salt in the canton of Vaud as a result of the efforts of the Swiss goiter commission,

⁶³ Report of the Initial Meeting of the Study Committee on Endemic Goiter of the American Public Health Association, Detroit, June 14-15, 1941.

⁶⁴ Marine, David and Kimball, O. P. Prevention of Goiter in Man. *J. A. M. A.* 77: 1068 (Oct. 1) 1921.

brought about in fifteen years a decline of goiter incidence from 77 to 21 per cent⁶⁵

The Iodized Salt Committee of the Michigan State Medical Society was organized in 1922. Common salt, iodized to contain 0.02 per cent of sodium iodide, was subsequently introduced by that committee in cooperation with the state board of health in 1924. The results of its consumption were convincing. From 1924 to 1935 there ensued a 75 to 90 per cent decrease in the incidence of goiter in those counties using the iodized salt.⁶⁶ The incidence of goiter operations in seven large hospitals in southern Michigan dropped from 1,452 in 1927 to 591 in 1933. There was a 60 per cent decrease in goiter operations as compared with a 17 per cent all operation decrease during the corresponding depression years.⁶⁷

Iodine supplementally administered in the form of iodized salt, when thus extensively used, has repeatedly proved beneficial in the prevention of goiter. Its curative effect, however, depends on the character of the goiter as well as on the patient's age at the time of institution of iodine treatment. While it is of value to patients with colloid goiters,³ little beneficial change may be expected in older patients with goiters of long standing in which there are extensive pathologic alterations such as hemorrhage with resultant cyst formation, calcification, vascular degenerative changes and old nodular formations.⁶⁸ The efficacy of iodine prophylaxis is greater the earlier it is applied and decreases after puberty.³ Consequently it would seem wisest to commence prophylaxis even before the time of conception and to maintain it throughout the pregnancy. It should be continued as well during childhood and particularly through the menarche in young girls. This can be adequately accomplished in iodine deficient goitrous regions by the continued use of iodized salt. Subsequent to the nearly worldwide preventive use of iodine a general decrease in the incidence of goiter has ensued, particularly in Switzerland, Austria, Germany, northern Italy, the United States, England, New Zealand, Poland, Rumania, Latvia and more recently in other countries.²⁴

Evident microscopic changes ordinarily occur in hyperplastic thyroids subsequent to the administration of supplemental iodine. Rapid involution of an existing hyperplasia may be induced, moreover glandular hyperplasia of the residual tissue even after extirpation of as much as three fourths of the thyroid can be prevented by the administration of sufficient iodine. Marne and Lenhart even maintain that a hyperplastic gland cannot revert to the colloid state without the presence of a necessary minimum of iodine.¹⁴

Despite almost worldwide favorable results thus empirically substantiating the basic theory behind iodine prophylaxis, objections have been repeatedly raised in the earlier years abroad and more recently in the United States to the preventive use of supplemental iodine. Principal among these objections has been the harm which iodine might cause to persons with overactive thyroid glands as well as the excitation of a simple or

nodular thyroid enlargement into a toxic or hyperfunctioning type. The basis of this fear of "jodbasedow," or *iodine induced hyperthyroidism*, arose as early as 1820 when Comdet treated his patients with excessive amounts of iodine.⁶⁹ The resultant idea has developed along with the subsequent progress of iodine prophylaxis. It has been a natural reaction to dangers inherent in pioneering a drug whose action was not fully understood. More recent exponents of the basic theory behind "jodbasedow" were Theodore Kocher and his successor Fritz de Quervain. In 1904 Kocher reported that patients with nodular forms of goiter may develop thyrotoxicosis when treated with iodine, in 1910 he wrote of the untoward effects of iodine in toxic diffuse goiter.⁷⁰ In 1933 de Quervain listed 33 cases of "jodbasedow" observed during a period of nine years.⁷¹

Convincing proof that iodine induced hyperthyroidism ordinarily or even commonly results from the administration of increased amounts of iodine to patients with goiter is lacking. On the other hand there is extensive evidence that supplemental iodine is ordinarily beneficial in the preventive treatment of endemic goiter. Kimball found that only 4 per cent of patients with goitrous "adenomas" later developed hyperthyroidism after the use of iodized salt, whereas 56 per cent of those with goitrous "adenomas" who used no iodized salt or any other form of iodine medication later manifested evidence of increased thyroid activity.⁷²

In current medical practice there is ordinarily but little hesitancy in prescribing relatively large amounts of iodide on specific indications for example in the therapy of syphilis without any special regard to the thyroid and its activity. Demonstrably harmful effects as a result of increased thyroid function are not expected and are rarely encountered, especially if patients with thyroid abnormalities are excluded.⁶ However symptoms of iodism ranging from a mild coryza or a moderate acne to a severe dermatitis even with high fever are known to occur subsequent to the administration of iodides.⁷³

No ill results should be anticipated from the widespread use of iodides in the minute concentrations in which they occur in iodized salt. The development of iodism subsequent to the continued use of iodized salt alone has even been questioned.⁷⁴ Nor is iodism subsequent to the consumption of diets rich in iodine-containing foods recorded in the literature.⁷⁴

IODINE PROPHYLAXIS IN ANIMALS

Breeding difficulties among domestic animals long existed in varying degrees throughout the goiter areas of the United States.⁷⁵ A practical solution of this

threat to the health of our country's live stock was found in the administration of iodine. As early as 1907 iodine-containing salts were fed to Michigan sheep in order to prevent the high death rate ordinarily occurring among the newborn.⁶⁰ In 1916 Montana, faced with a high mortality among its live stock, as well as with the development of goiter and underfunctioning thyroids, instituted similar therapy with considerable success.⁶¹ At the University of Wisconsin Farms, since the introduction of iodized salt in 1920, there has not been an instance of goiter among the domestic animals, including sheep, swine, colts or calves.⁶²

Iodine prophylaxis of iodine deficiency disease among animals, or "fetal athyrosis," as it is designated, has spread to various other states and provinces. Minnesota, North and South Dakota, Wyoming, Washington, Idaho, southern Alberta and British Columbia have similarly used iodine preventively.⁶³

IODINE AND THE GENERAL HEALTH

Sufficient iodine is requisite for normal growth.³ As early as 1895 it was demonstrated that growth may be induced even in certain cretins by the administration of dried thyroid. A similar effect may be demonstrated in certain children, living in iodine deficient areas and not receiving supplemental iodine, who have failed to grow normally because of lesser degrees of hypothyroidism. These children may also manifest various other symptoms subsequent to varying severity of the hypothyroidism.⁷⁰

Topper and Cohen record that the administration of desiccated thyroid to normal children, as well as to children presenting evidence of hypothyroidism, resulted in definite growth acceleration in both groups.⁸⁰ Swiss statistics show that boys receiving iodine grew on the average 7 mm more than untreated boys and put on 200 Gm more of weight. The mean weight at birth of infants whose mothers were receiving iodized salt was 100 Gm greater than that of control infants.³

Hunziker reported that the average height of Swiss recruits was significantly greater from 1908 to 1912 than during the period from 1884 to 1891. He concluded that supplemental iodine was partly responsible for this increase in stature. Moreover, he found the average height inversely proportional to the incidence of goiter in the sections from which the recruits came.⁸¹

Feeding milk with an increased iodine content to children living in a region of high goiter incidence resulted in more rapid and regular growth and development. Children with debility or those who revealed slow development, failure to gain weight or retarded growth showed subsequent steady improvement.⁸² Administration of optimal amounts of iodine to nursing animals

accelerated the rate of growth and weight of their young.⁸³ Direct iodine administration to the young was likewise beneficial.⁸⁴

The favorable effect of iodine on the growth of vertebrates may be direct or indirect. It appears more likely that iodine acts indirectly by supplying the necessary constituent for normal thyroid secretion and thus permitting the gland to exert its usual function. Excessive thyroid secretion limits growth and may result in abnormal development.⁸

THE HUMAN REQUIREMENT OF IODINE

The human organism thus has a definite nutritive requirement for iodine. The supply necessary to answer this demand should be sufficient to meet the daily losses by excretion and to maintain within the body such a reserve as may be needed in the manufacture and distribution to the body of sufficient thyroid hormone. The amount of iodine intake, however, is not always equal to the physiologic needs. Elmer points out the contrast with the organism's chlorine requirement which is associated with the sensation of taste.⁴ The fundamental question consequently arises: how much supplemental iodine should be supplied in goitrous areas to protect the people and live stock from the effects of iodine deficiency? Thus far, three methods have been devised in attempts to answer this question.

By the geographic method the iodine intake of the inhabitants of goiter free areas is determined and compared with that of goitrous areas of varying degrees. The difference in the amount of iodine intake is then regarded as the amount of supplemental iodine required. According to von Fellenberg's estimate the annual iodine intake in one goitrous and one practically goiter free area in Switzerland was 4.7 and 11.4 mg respectively.⁸⁵ Calculating from this the iodine requirement is less than 20 micrograms daily, a figure now regarded as unusually low. Calculated on a survey of the average daily urinary loss of iodine which is an unusually accurate barometer of the iodine intake of a given area, the daily iodine requirement would lie somewhere between 100 and 200 micrograms.⁴⁰

The principle of thyroxine formation and decay was originally outlined by Plummer and Boothby⁸⁶ and subsequently developed by W. O. Thompson and his associates.⁸ Plummer and Boothby found that the daily rate of thyroxine decay ranged between 0.2 and 0.4 mg. Thus, this daily supply of thyroxine maintained a normal basal metabolic rate in a totally myxedematous patient. Thompson and his group concluded that from 0.3 to 0.4 mg of thyroxine was necessary to

maintain a normal basal metabolic rate in myxedematous patients at bed rest. On the basis of these results the amount of thyroxin supplied daily by the thyroid to the circulation in order to maintain normal metabolic activity is equivalent to from 130 to 260 micrograms of iodine. The uncertain factor here, however, is that iodine-containing end products of thyroxin decay may be retained and eventually reutilized by the thyroid gland in the further synthesis of thyroid hormone.

Total iodine balance studies constitute the third principle which has been employed. The iodine balance represents the daily amount of iodine lost or retained by the body, as ascertained by the difference in the amount of iodine intake and excretion. Pioneer iodine balance determinations were accomplished by von Fellenberg, who reported low values and consequently a low daily requirement.⁸⁷ The balance studies of Scheffer made in Pecs, Hungary, revealed that 54 micrograms of daily iodine intake was sufficient to maintain a normal individual in iodine balance.⁸⁸

Ohio State University studies were made on normal individuals maintained at bed rest on a monotonous diet under controlled hospital conditions (charts 1, 2 and 3). Under these circumstances the basal human adult iodine requirement was found to range from 44 to 75 micrograms daily and to average 67 micrograms, or approximately 1 microgram per kilogram of body weight.⁸⁹ This average daily requirement is comparable to that determined by Scheffer. However, it should be emphasized that it applies to adults maintained under controlled basal conditions. Moreover, to arrive at an optimal iodine requirement, it is necessary to take into account individual activity as well as the varied stress and strain of existence.

After consideration of the difference in iodine intake between goitrous and nongoitrous regions, as well as the amount estimated as necessary to maintain normal metabolic activity, 2 micrograms daily per kilogram of body weight, together with the daily basal requirement of 1 microgram, can be reasonably justified as an amount sufficient to account for basal needs, those of ordinary activities and also some for reserve. The optimal daily requirement would thus be somewhere near 200 micrograms for the 70 Kg. adult, a value compatible with Elmer's deduction from various investigations that the human optimal requirement ranges between 100 and 200 micrograms daily.²⁴ The pregnant woman should receive additional iodine.⁹⁰

Various methods of supplying supplemental iodine to the inhabitants of iodine deficient areas have been advanced. These include the use of foods known to be rich in iodine, iodination of water supplies, administration of iodine at regular intervals in the form of solutions or tablets, the general use of iodized salt and the consumption of iodized milk.

The use of iodized salt has thus far proved the most widely adopted method. The nearly universal employment of common salt for seasoning and cooking as well as the ready preparation and low cost of iodized salt makes this a popular method. The use of milk with an

increased iodine content has also been suggested as suitable, especially for children who ordinarily consume relatively large quantities.⁹¹ Effective iodine prophylaxis, however, should also conform to local conditions, since no single method will reach all those individuals who need iodine.⁹²

On June 14, 1941 the National Study Committee on Endemic Goiter, meeting in Detroit, resolved that

On the basis of past experience in Michigan and taking into consideration more recent laboratory research, the committee recommends that for the prevention of endemic goiter the content of potassium iodide in table salt and salt for domestic animals should be 0.01 of 1 per cent, provided that an effective stabilizer be used.⁹³

The iodized salt originally recommended in 1924 by the Michigan State Medical Society in conjunction with the state board of health, and since employed in Michigan with such outstanding results, originally contained 0.02 per cent of sodium iodide, or more than twice the amount of iodine recently recommended by the National Study Committee on Endemic Goiter. However, after careful consideration the committee reached the conclusion that the addition of 0.01 per cent of potassium iodide plus a stabilizer should be sufficient. The importance of a stabilizer was emphasized in view of previous experience that iodine may be lost from iodized salt and thus impart a yellow color and halogen odor due to the liberation of elemental iodine.

It has been estimated that the average adult ingests about 6.2 Gm. of salt daily. Calculated on this basis, the approximate amount of potassium iodide intake would be 620 micrograms, which is equivalent to about 474 micrograms of iodine. This is more than twice the amount we have suggested as optimal and would amply provide a person with a sufficient reserve.

The widespread prevention of endemic goiter and its sequelae will depend not only on the preparation and consumption of an adequate iodized salt but also on the persistent education of the public to its necessity.

I am sure you are aware that in spite of the notable contributions of Michigan and the organization of similar practices in a few other states there are still a good many states in the country where goiter is a problem with a portion of the population, where no thought is given to it where there is no state health policy and no professional medical attitude and where endemic goiter prevails, and in a severe form. Our interest in the American Public Health Association is to get the facts so authoritatively expressed and accepted that there can be no escape from the responsibility of the health officers to make effective all useful methods of goiter prevention. (Dr. Haven Emerson)⁹³

Under ever increasing demands of wartime effort and production each individual should have, to thrive and function at his best, among other important elements an adequate supply of iodine. For iodine, not only a nutritional necessity in the prevention of goiter, plays an important role in the general well-being of all mammals. The increased physical activity and emotional stress occurring in our struggle for survival put greatly increased demands on the human body. Thus the optimal activity essential for any all inclusive war effort cannot be maintained without a sufficient supply of iodine.

Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT
AUSTIN E SMITH MD Secretary

AMPULS OF CAMPHOR AND ACCEPTED
BRANDS OMITTED FROM N N R

The following manufacturers' brands of Ampuls of Camphor have been included in New and Nonofficial Remedies George A. Breon & Co., Inc., Drug Products Company, Inc., and Endo Products, Inc.

At the October 1941 meeting of the Council the question of the present usefulness of ampuls of camphor was discussed but definite action was postponed in order that a status report could be prepared

On the basis of a subsequent report the manufacturers of accepted camphor preparations were informed that the therapeutic usefulness of camphor had been questioned and that they were therefore invited to present any available evidence which would justify its further retention in New and Nonofficial Remedies. A letter was also directed to authorities on agents used to combat circulatory collapse asking for an opinion on the usefulness of this drug.

Reply was received from only one manufacturer, who stated "this product is not used as extensively as heretofore and we have no defense to offer for its retention in the N N R"

Of the authorities consulted on this problem, eleven replied

DR JOHN MARTIN ASKEY, Los Angeles My only experience with camphor parenterally was during my hospital years from 1923 to 1925 and a year or so after that I was unable to convince myself that there was any beneficial effect from the camphor and consequently I have not used it for the last twelve or thirteen years

DR M A BLANKENHORN, Cincinnati It has been so many years since any one on my service has used camphor oil for intramuscular use that I am obliged to look elsewhere for an answer to your question I cannot find that any one in the Cincinnati General Hospital has used enough camphor oil within the past ten years to have any opinion about its value The pharmacist has a canny way of telling what the vogue in therapy has been in this hospital for a long period He is very sure that no one has used any within the past two years, and in the past ten years so little has been used that it would be impossible to give an opinion about its value I should tell you that in this hospital the resident staff is given a great deal of authority in selecting remedies and the visiting staff, many and varied, is likewise given to try everything My conclusions are that camphor oil has been abandoned

DR HERRMAN L. BLUMGART, Boston I have not utilized camphor for many years, since I have never been able to convince myself that the administration of this substance parenterally was really useful. Particularly in recent years, other substances have become available which have more definite therapeutic usefulness.

DR HENRY A CHRISTIAN, Brookline, Mass I consider camphor as of very little value in circulatory and respiratory collapse, however it is given Commencing in 1907, after seeing it used extensively in Germany, I used camphor in a mixture of oil and ether subcutaneously and intramuscularly both in postoperative and postinfectional circulatory respiratory collapse or failure Results were disappointing and I substituted caffeine in large doses, often intravenously, with more satisfactory results I do not advise continued acceptance in New and Nonofficial Remedies

DR HAROLD FEIL, Cleveland I have never had any very definite feeling about the merits of camphor and do not use it. Certainly there are more effective ways of stimulating the myocardium and I feel that camphor is not an important drug in heart therapy.

DR HARRY GOLD New York I am of the opinion that camphor has no value for systemic use, either by injection or by any other mode of administration, in the treatment of circulatory collapse or heart failure. Some years ago I made a study at the hospital on a select group of patients with circulatory failure and heart failure with congestion. I recorded the blood pressure, heart rate, urine output and symptoms that would indicate improvement. Camphor in oil was injected intramuscularly in doses of 10 grains every hour. The highest total amount was 106 grains. There were no signs of improvement by any of the foregoing criteria. The largest dose caused extreme nervousness with a panic state and diarrhea. These patients responded in the customary way to subsequent digitalization. In some of these patients, peripheral circulatory failure was outstanding and, in these as well, camphor was without therapeutic effect. The literature on the beneficial effects of camphor on the circulation is notoriously uncritical.

DR E E IRONS, Chicago For many years camphor was one of the drugs that was used in emergencies as a cardiac stimulant. Some men used it in alleged cardiac failure in pneumonia. I always felt it was used chiefly because there was nothing much else to do. I have not used a dose of camphor as a cardiac stimulant for twenty years.

DR LOUIS N KATZ, Chicago I see no need for continuing camphor in New and Nonofficial Remedies This drug is now used but seldom, and at no time did it seem to have any universally expected action While it has been used as a heroic procedure to resuscitate persons by so called respiratory and circulatory stimulation these effects if present were fleeting and probably produced by reflexes set up by the irritation of the drug locally As a stimulant it has been largely replaced by nikethamide, by metrazol and by caffeine I have inquired among my clinical colleagues and have been informed that they rarely or never use it Not one has considered it important that it be retained in the N N R Our drug room has had a supply on hand which is seldom called on There was a vogue amongst pediatricians for its use many years ago, but this too has died out I therefore see no reason for retaining this drug The most that can be said for it is that it is harmless, but even this carries with it the possibility that a physician in using this drug may overlook the use of something potent

DR ROBERT L LEVY New York There is no evidence that camphor, no matter how given, is of value in circulatory collapse or heart failure. Such action as it has is of very short duration. There are numerous other drugs and therapeutic measures which are more effective in treating these conditions. In my opinion ampuls of camphor should be dropped from the forthcoming edition of "New and Nonofficial Remedies."

DR EUGENE A STEAD JR, Atlanta, Ga As far as I know, there is no satisfactory evidence that camphor is useful in the treatment of collapse My own reaction would be not to include it in New and Nonofficial Remedies I am not familiar with any recent literature on this problem

DR HAROLD J STEWART, New York In the last twenty years of my practice in internal medicine with special emphasis on cardiology and diseases of the cardiovascular system I have not had occasion to use camphor in any form and from my own experience see no place for its use

Since none of the manufacturers or the specialists who would ordinarily be familiar with an agent widely used in their field have offered evidence to justify retention in New and Non-official Remedies, it was believed that the chapter on camphor preparations should be omitted immediately without waiting to give the matter further consideration in 1943, which is the expiration date of the products now accepted.

In view of the foregoing, the Council voted to omit the chapter "Ampuls of Camphor" and the accepted brands from New and Nonofficial Remedies in view of the absence of evidence to justify retention.

COOLING IN SHOCK

The use of external heat to treat or prevent shock is a time honored remedy like the treatment of fever with cold applications. These measures once seemed wholly logical. Means of lowering body temperature in febrile states are now generally used only when the temperature rising over 104 F, causes delirium and threatens life. Fever is recognized as part of the "wisdom of the body." The concept of the possible protective role of reduced temperature of the body or the extremities in shock has not been given sufficient consideration. Warnings about the dangers of overheating are appearing with increasing frequency in current writings.¹ Many thoughtful surgeons long ago abandoned the "postoperative sweat" treatment or "shock bed" which was introduced primarily in the hope of preventing shock and pneumonia.

The patient who is going into shock may feel uncomfortably warm, just as does the one who is about to faint. This may be considered the converse of the "chill" that accompanies the rise in temperature at the onset of fever. A chill obviously is a mechanism for raising body temperature rapidly, the feeling of warmth, like the sweat after a chill, is part of the bodily mechanism for rapidly lowering body temperature. No one has proved that a patient's sensation and behavior when he has a chill or a sweat are harmful and not a part of a complex adaptive mechanism. Many of us have had the unfortunate experience of finding 'well trained' people working hard to warm up a patient with cold, clammy skin when the rectal temperature was found to be 105 or 106 F, much to the consternation of all concerned except the patient who by this time had ceased trying to remove the covers.

Patients in shock look better when heated, just as febrile patients may feel better after the use of antipyretics. In animals shocked by various procedures a temporary improvement in appearance is produced by warming, but this may be followed by rather sudden

collapse. The warmed animals show a higher death rate than the unheated or cooled controls.² Analogies between shocked animals and the complex types of shock seen in modern war cannot be too closely drawn, work on higher apes is needed to round out the observations on rodents and dogs. However, it is certainly true that when blood volume is reduced the oxygenation of the tissues is restricted. When the oxygen supply is thus reduced, survival depends partially at least on the temperature. The cooler the tissues the less the oxygen requirement. The fall in metabolism amounts to about 13 per cent for each degree centigrade.

Much harm is attributed to tissue anoxia in shock. Subnormal temperature tends to prevent relative anoxia by diminishing the speed of the vital use of oxygen. Thus a fall in temperature is not the result of the anoxia but rather seems to be a well developed and useful protective mechanism which the traditional treatment combats. In this connection it is interesting to note that many have been surprised at the recovery of casualties who did not have the "benefit" of prompt professional care.

The safe range of body temperature deviates far more below than above normal, temperatures down to 90 F can be tolerated for many hours and may actually be life saving when the circulation is feeble. Experimental and clinical studies have resulted in abandonment of the old enthusiasm for warmth in the treatment of an extremity with impaired circulation and threatened gangrene. We have agreed not to fight nature's cooling of the foot that is suffering from anoxia but we are still training first aid workers to fight nature's cooling of the person who has a general inadequacy of circulation. Traditional views about the relation of external heat to shock have retarded acceptance of refrigeration (crysto-) anesthesia in traumatic lesions of the extremities. Those who have used it are impressed by the fact that the method seems to reduce rather than increase the dangers of shock.

Investigators are still at work analyzing the mechanism and the nature of heat exhaustion. All recognize that it has the characteristics of shock—cold, clammy skin, oligemia and hemoconcentration. One form of shock is therefore produced by heating the body, and heat prostration is not treated with hot packs. A large incidence of heat prostration often comes with sudden onset of hot weather, when the existing blood volume is insufficient for the increased demands imposed by vasodilatation and sweating. Heating the postoperative or post-traumatic patient makes the environment comparable to the beginning of hot weather and thus adds to the danger of insufficient blood volume, shock or heat prostration.

Warming the shock patient has been practiced for centuries without convincing evidence of value. Cooling has not apparently been given a fair trial. Many

¹ Blalock, Alfred and Maon, M. F. A Comparison of the Effects of Heat and Thaw of Cold in the Prevention and Treatment of Shock. Arch. Surgery 42: 1054 (June) 1941.

² William, John R. Winston-Salem, N. C. Personal communication.

experimental studies are still unpublished because of laudable caution. The time is now ripe for a presentation of the side of this complicated and controversial subject which favors cold. Certainly external warmth should not be used in treating cases of shock when only the skin is cold but rectal temperature is normal or even above normal.

The following points deserve emphasis, particularly in teaching outlines for first aid workers, which incidentally should be modernized at once by eliminating those portions dealing with external heat for the alleged prevention or treatment of shock. Aiding the cooling process during certain phases of shock by cold applications seems theoretically sound, but the use of such procedures should await further knowledge. External heat makes the shock patient appear better but probably lessens his chances of recovery. A conscious patient should be warmed or cooled in accordance with his own desires. An unconscious postoperative or post-traumatic patient needs no more external warming than a recumbent normal person. Hot water bottles, hot pads and hot blankets are usually not indicated unless they are necessary also for normal persons in the same environment. External heat should never be applied when the rectal temperature is above 96 F. Coldness of the skin often conceals a rise in body temperature. In the long and bloody war that lies ahead, shocked soldiers have a better chance of recovery than ever before because of the use of plasma and other means of restoring blood volume. It will probably be still better if therapists abandon the fight against the wisdom of the body in lowering the oxygen needs by cooling. Instead of warming the shocked patient, allow him to maintain the lowest safe level of temperature.

INFLUENZA EPIDEMICS

An influenza epidemic, once well under way, is spread by droplets. What happens at the beginning of an outbreak? Why do epidemics occur only at intervals? In his recent presidential address before the Section of Pathology of the Royal Society of Medicine, Andrewes¹ reviewed the present knowledge of this subject and presented theoretical considerations which he believes may explain some of the obscurities.

There is a tendency, Andrewes says, to interpret recent observations as meaning that epidemics are caused by numerous different viruses, only two of which have yet been recognized. However, there may be more unity in influenza than such a view would suggest. In epidemics of meningitis, he points out, the different serologic types are spread simultaneously. Indeed, in time of war and famine, wholly distinct diseases such as typhus fever, relapsing fever and dysentery may rage at the same time. Thus the yet unknown

subtle factors which determine an influenza epidemic may similarly favor the spread of 'influenza A' virus and at the same time of B and perhaps of C and of others.

Swine influenza breaks out in herds of pigs in the Middle West every winter, but the virus apparently disappears every summer. A clue to the mysterious sudden occurrence of swine influenza may be afforded by Shope's² observations on the survival of swine influenza virus in lungworms, which are almost universally present in pigs' lungs in the Middle West. In a pig with swine influenza, the lungworms in its lung take up the virus. This is present in the embryonated ova, which duly pass out through the pig's alimentary canal. The intermediate host of the lungworm is the earthworm. The earthworm consumes the lungworm ova which have been passed in the pig's feces and the lungworms go through further phases of their life cycle within the earthworms. In due course pigs eat these infected earthworms. Then the lungworms find their way through the pig's intestinal wall to the lungs—still carrying the influenza virus throughout their travels. The infected pig does not at once get swine influenza, some provoking stimulus is necessary to activate the disease. In Shope's experiments the most regular way of activating the infection was to give repeated intramuscular injections of live or killed *Haemophilus influenzae*. However, intrapulmonary injections of calcium chloride and other apparently unrelated but similar "insults" to the pig have provoked the disease. Andrewes concludes that the natural epizootic occurring simultaneously in every one of a herd of pigs can be explained by the action of a provoking stimulus—just what is not exactly clear—to animals already harboring the virus infected worms in their lungs. As far as human epidemics are concerned, a helminth reservoir of virus is not inconceivable but does not seem likely. However, the story of the swine virus does emphasize the possibility that an influenza virus can exist in a masked or occult form.

Another puzzling question is the relationship between active immunity to influenza and the titer of circulating antibodies. What are the difficulties? First there are periodic outbreaks of influenza, the major ones are apparently due chiefly to "influenza A", others may be due wholly or partly to "influenza B", still others may produce cases which fail to show signs of the presence of the influenza virus as at present known, although the illnesses are clinically like those of known 'influenza A and B' virus infections and occur simultaneously. Second, "influenza A" viruses vary from one outbreak to another, antigenically, in their rapidity of spread in the human population and in the ease with which they can be established in ferrets. Third it has been shown

1 Andrewes C. H. Thoughts on the Origin of Influenza Epidemic. *Proc Roy Soc Med* 36: 1 (Nov.) 1942.

2 Shope R. E. Swine Lungworm as Reservoir and Intermediate Host for Swine Influenza Virus. Transmission of Swine Influenza Virus by Swine Lungworm. *J Exper Med* 74: 49 (July) 1941.

that "influenza A" virus lies quiescent for twenty-one months out of twenty-four. Fourth, some relationship is shown to exist between the immunity of an individual and the level of neutralizing antibodies in his serum, yet protein antibodies diminish only to a limited extent his liability to infection. As a possible solution, Andrewes pictures a "basic influenza virus," stripped of a number of its properties including all or most of the A antigen, which makes it recognizable serologically as "A influenza" virus. It would then resemble the degraded forms of many bacteria which exist in a form lacking a familiar antigen. This basic virus may then, according to Andrewes' theory, be presented as a latent virus, persisting harmlessly in cells of human carriers, although the possibility that it hides in some other host between epidemics cannot be ruled out.

How, then, may this basic virus acquire the virulence to produce the influenza epidemic or pandemic? In winter when other respiratory pathogens pass from host to host more easily, this "basic virus" is helped to travel too, by chance passage through several successive hosts with low A antibody or otherwise poor resistance its virulence and power to make an antigen may increase. Following this line, Andrewes postulates different gradations of virus: grade 1, a basic virus which probably spreads little but remains between epidemics in a small number of human carriers; grade 2, the hypothetical agent causing a large number of those cases of influenza which occur mixed with "influenza A or B" but get labeled "influenza Y" because no evidence of the workings of A or B can be detected; grade 3, the agent which has developed the ability to infect ferrets and to make much A antigen; grade 4 (resting on firmer ground), the agent from which patients develop readily obtainable A antibodies during their illness; and grade 5, viruses which caused widespread epidemics in Great Britain in 1933 and 1937 and which infect ferrets and mice with relative ease. There is not yet enough information, Andrewes says, to guess what grade of virulence must be obtained before amniotic inoculations, as described by Burnet,³ can be successful. What relationship exists between the viruses involved in the pandemics of influenza of 1918-1919 and the epidemics of the last decade is likewise speculative.

As Andrewes himself says, this outline of a gradation in properties of influenza viruses from basic virus to pandemic virus may prove to be far from a true picture. If true, however, it would afford a feasible explanation of many difficulties—of the failure to find A virus between epidemics, of the occurrence in many outbreaks of mixtures A and Y, of the variations in biologic properties of viruses isolated at different times and of the anomalies in the relation between antibody titer and active immunity. If this sequence of events is

essentially correct, it might result in possibilities of interrupting the cycle at several different points. Most important, it could be attacked at its beginnings when virus of low grade is being given an opportunity to spread widely. Moreover, this conception may affect the possibilities of improving aerial hygiene in the future by better ventilation, ultraviolet radiation and antiseptic mists and may offer a clue to the more effective utilization of biologic methods of active immunization.

Current Comment

THE NATIONAL QUININE POOL

This week to every druggist in the United States went from the War Production Board an appeal for quinine, supplemented with statements by Ross T. McIntire, Surgeon General of the Navy, Donald M. Nelson of the War Production Board and Jesse H. Jones, Secretary of Commerce. The Army and Navy need every gram of quinine that can be secured. "Even though atabrine and other synthetic antimalarials are being used in tremendous quantities," says the statement, "quinine is vitally needed for our soldiers abroad because this drug has a faster action, brings the malaria under control more quickly, and thus shortens the length of time the soldier is incapacitated. Quinine is also necessary for use in cases which cannot tolerate atabrine and other synthetic drugs." The needs of our civilian population for antimalarial drugs will be cared for by the development of totaquine, which is a mixture of cinchona alkaloid prepared from the low grade barks in South America. Totaquine, while excellent for domestic use, is not as stable as is quinine and therefore not as suitable for shipment into areas of varying climatic conditions. To the pharmacists of the country the appeal has been made that they send all supplies of quinine, alkaloids, salts and other cinchona derivatives, whether in open or in closed packages, to the National Quinine Board, which is in the headquarters of the American Pharmaceutical Association, 2215 Constitution Avenue Northwest, Washington, D. C. These materials, when collected, will be processed and thus made available to our armed forces. Each druggist who makes a contribution will be privileged to display in the window of his store a card indicating that he has contributed to the National Quinine Board and thus has rendered an important service to the armed forces. At the same time as this arrangement was being put into effect in this country, an announcement came from Great Britain that drastic restrictions have been placed on quinine, making it illegal to prescribe, dispense or supply quinine except in the treatment of malaria or in the case of quinidine in the treatment of cardiac arrhythmia. So important is the control of malaria to the health of our troops in many of the combat zones that the supply or lack of quinine might well be the determining factor in the winning of the war.

AMERICAN PHARMACEUTICAL MANUFACTURERS' ASSOCIATION AWARDS
SCROLL OF DISTINCTION
TO DR DOISY

Since 1939 the American Pharmaceutical Manufacturers' Association has recognized annually the achievement of a scientist who has distinguished himself in the field of therapy. The award is made on the recommendation of an advisory committee which includes Dr George R. Cowgill of Yale University School of Medicine and Dr Howard B. Lewis of the College of Pharmacy of the University of Michigan. Those who have received awards since 1939 include

1939 Drs Nathan B. Eddy and Lyndon F. Small, United States Public Health Service, for studies of chemistry, pharmacology and therapeutics of morphine derivatives

1940 Dr Perrin H. Long, Johns Hopkins University School of Medicine, for studies of sulfanilamide, sulfapyridine and related pharmaceuticals

1941 Dr Tom D. Spies, University of Cincinnati School of Medicine, for contribution to our knowledge of the B complex vitamins as pharmaceuticals important in the treatment of disease

1942 Dr Edward A. Doisy, St. Louis University School of Medicine, for fundamental scientific contributions in the field of hormones

Each year the scroll which memorializes the contribution to science is presented by a distinguished physician in the presence of an audience composed of leaders in the scientific and industrial field and is accompanied by a symposium devoted to the phase of medical science in which the recipient of the award has achieved distinction. Awards such as this, which represent recognition of distinguished service to humanity, have a special place in the field of medicine, and the American Pharmaceutical Manufacturers' Association deserves commendation for the high plane on which the selection of the recipient and the manner of the presentation have been maintained.

VIRAL CHEMOPROPHYLAXIS

In the course of experiments to determine what dietary factors are essential to multiplication of virus, Sprunt¹ of Duke University found that subcutaneous injection of methionine in rabbits increased their dermal resistance to experimental inoculation with vaccinia virus. Measurements of skin susceptibility were made by use of serial dilutions of the virus, the 50 per cent point being selected in calculations of the immunity ratio.² In a typical experiment 5 rabbits each received a daily dose of 300 mg of methionine for two days preceding and five days following dermal injection with the virus, 5 normal rabbits of the same age and weight being used as controls. In this series the calculated dermal resistance was increased fourteenfold as a result of methionine therapy. If the first methionine dose was delayed till immediately after the skin test, the calculated increase in resistance was tenfold. If delayed till forty-eight hours after the skin test, the increase was but fivefold. In all cases the lesions in the treated animals were smaller in size and disappeared twenty-

four hours earlier than in the controls. Equally striking results were obtained with choline, given in 300 mg doses at eight hour intervals two days before and continued for five days after the skin test the calculated dermal resistance in the choline series being increased nineteenfold. Betaine caused a similar but less pronounced increase in skin resistance the calculated ratio here being fivefold. The chemical characteristic common to these three successful prophylactic agents is the "biologically labile methyl group." Whether or not exposed mucous surfaces share in this therapeutically increased viral resistance has not yet been determined. Viruses other than poliomyelitis virus have not yet been tested.

FRANCIS X. DERCUM

The name of Dercum is probably best known to the medical profession for his description of a neurologic entity, *adiposis dolorosa*. Dr Throckmorton,¹ who studied under Dercum, gave a vivid picture of him in his chairman's address before the Section on Nervous and Mental Diseases of the American Medical Association at the Cleveland session in 1941. Francis X. Dercum was born in Philadelphia, Aug. 10, 1856. On his graduation in 1877 from the University of Pennsylvania he engaged in the general practice of medicine in his native city. From the beginning his interests were wide, as is evident from the fact that he taught histology and physiology in his alma mater, while paying more and more attention to the diseases of the nervous system. In 1884 he was appointed consultant pathologist to the State Hospital for the Insane at Norristown. Somewhat later he succeeded Dr Charles K. Mills as chief of the Nervous Disease Clinic in the Hospital of the University of Pennsylvania and instructor in nervous diseases at the university. In 1885 he became one of the founders of the Philadelphia Neurological Society, whose first president was S. Weir Mitchell. In 1887 he was appointed neurologist to the Philadelphia General Hospital, the famous Old Blockley. Here he was actively engaged in teaching and clinical work for a quarter of a century. In 1892 he was elected to the newly created chair of clinical professor of neurology in the Jefferson Medical College, where he taught nervous and mental diseases until 1925. In 1892 he published a paper in which he described a new entity to which he gave the name *adiposis dolorosa*. This became known as Dercum's disease. Dercum was a talented clinical investigator, an inspiring teacher and a philosopher. His philosophic tendency is best reflected in the last two books written by him, "The Physiology of Mind" and "The Biology of the Internal Secretions." The government of France made him a chevalier of the Legion of Honor, and the American Philosophical Society elected him president. His last contributions were "On The Nature of Thought and Its Limitation" and "Nonliving and Living Matter." Death came to him suddenly, April 23, 1931, while he sat in the presidential chair of the American Philosophical Society.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

EXPERIMENTAL MEDICINE IN RUSSIA IN THE WAR

PROFESSOR LAURENTIEV

(Supplied by the Russian Embassy)

The All Union Institute of Experimental Medicine (VIEM) is the greatest medical research institute in the Soviet Union. Recently it celebrated its fiftieth anniversary. Besides I. Pavlov and Svirich many conspicuous scientists are associated with the institute, including Bykov and Speranski.

Shortly before the outbreak of war against Germany, the institute had two leading scientific centers, located in Moscow and in Leningrad and a special biologic station with a monkey nursery at Sukhumi in the Caucasus.

Of particular interest in the studies carried out by I. P. Pavlov and his school is the production of the nervous diseases and neuroses in animals. Evidence from extensive investigations undertaken in the department of pathology, headed by Academician Speranski, showed the leading role of the nervous system in human conditions of disease.

Among the clinical studies are those by Prof. A. V. Vishnevsky in local analgesia.

The invasion by Germany set before the institute two great problems which had to be solved as promptly as possible to alter the character of the problems pursued in the institute and to secure the productive research work in wartime. Decentralization of the institute was carried out and a number of its laboratories were transported far to the rear. In July 1942 a session of the institute was held in Novosibirsk to summarize its achievements during the first year of war.

A. Smorodintzev has developed a method of prompt diagnosis of typhus. This method enables one to diagnose typhus on the second or third day of the disease and thereby to prevent its dissemination. Dr. Levkovich prepared vaccines against typhus following all existing methods (Weigel, Duran-Spairo, Cox). These were tested on laboratory animals, as well as in clinics of the institute. Professor Petrisheva developed prescriptions of diverse extracts, preparations and ointments protecting man against lice. The chemical laboratories of the institute have found important diagnostic symptoms for identifying typhus. This concerns a peculiar chloride crisis undergone by the patient on the seventh day of the disease, chlorides disappearing from the urine to reappear again toward the end of the disease.

The bacteriophage laboratory headed by Professor Eimoliev has produced active phages against dysentery, pus-forming cocci and cholera. Some interesting combinations of phage with modern chemotherapeutic substance (sulfapyridine and sulfathiazole) are proposed by this laboratory.

Application of chronometric methods to the injured and uninjured nerve was proposed by Prof. A. Magntsky as a means for ascertaining the lesion of the nerve stem without recourse to an operation. This method is now used in hospitals. In the laboratories of Professor Anokhin and Kharitonov, the causes of pain accompanying lesions of the nervous system have been ascertained and the methods of eliminating them proposed. Combating pains, acceleration of the nerve regeneration and the prevention of irregular growth of the nerves are at present the most important problems of neurosurgery. So far hospitals and physicians have been very pessimistic regarding the replacement of defects of the nervous system. Dr. A. Anokhin suggested a method of replacing defects of the nerve stems by transplanting human and animal nerves preliminarily treated with formaldehyde. Many clinical cases have already been treated by using this method.

A special study of regeneration of the nerve and of the methods which may prevent its irregular growth and accelerate regeneration were carried out in the laboratory of Professor Lavrentiev. The method was devised of observing the regeneration of nerves in a live animal by means of vertical microscopic illumination. The great role of blood vessels was ascertained which were shown to change and develop within the damaged area of the nerve stem.

Injuries of the brain were studied in the clinics of VIEM headed by Professor N. Geraschenkov. The work of the nerve clinic in VIEM was organized in such a way that observations on the wounded were begun at a dressing point at the front and completed in the rear at a hospital. This offered the possibility to follow both the healing process of the wound and the results of the preventive and curative treatment. In treating cerebral wounds surgical methods were combined with intravenous and administration by mouth of modern chemotherapeutic substances such as streptocide, sulfidim and sulfithiazole which led to a great decrease in the mortality rate. The successful treatment of dangerous complications of skull wounds, as caused by microbes of gas gangrene, was devised. Professor Kaplinsky and Professor Braunstein showed that long lasting pains elicit appreciable metabolic changes, closely resembling those associated in the human and animal organism with vitamin B deficiency and the deficiency of this vitamin causes in its turn an inflammatory process in the nerve. This treatment, with large doses of vitamin B proved effective.

Besides the common methods of treatment with heat, the electric current and light the VIEM clinic inaugurated occupational therapy. A wounded fighter gets

gradually accustomed to movements associated with labor processes, such as sewing, hammering and planing. In this way the nervous system and limb are gradually reorganized and begin to perform movements which were impossible prior to the treatment.

The treatment of wounds of the suppurative processes of the joint and bone inflammations was taken up by

the surgical clinic in V.I.E.M. Prior to the war Prot A. Vishnevsky suggested treating the wounds by means of plugs soaked in an emulsion of balsam tar and similar substances with an admixture of xerotorm. This method proved exceptionally effective in treating large wounds—those of the chest and abdominal cavity included.

ARMY

CIVILIAN PHYSICIANS TO BE EMPLOYED BY ARMY FOR SERVICE IN WAR PLANTS

Civilian physicians with civil service status will be employed by service commands for medical service in industrial plants operated by the Army to relieve medical officers for troop duty. The War Department announced on January 26. Expert medical supervision is provided to insure industrial hygiene in army-operated arsenals and depots. In establishments where the work involves occupational health hazards, periodic physical check-ups of the workers are conducted. Women physicians may be employed at army plants at the discretion of the commanding officer. This practice has been recommended for plants employing a high percentage of women. A civil service examination announcement for physicians and civil service forms 57 and 2398 to be used in making application may be obtained at any first or second class post office.

THE McCLOSKEY GENERAL HOSPITAL

The U. S. Army General Hospital at Temple, Texas, has been named in honor of Major James A. McCloskey, M. C., the first regular army medical officer to lose his life in the present war with Japan during the battle of Bataan, Philippine Islands, in March 1942. Major McCloskey graduated from the St. Louis University School of Medicine in 1933, became a first lieutenant of the U. S. Army medical reserve corps on June 6, 1933 and was on active duty from Jan. 22, 1935 to Jan. 29, 1936; he was commissioned a first lieutenant in the medical corps of the U. S. Army on Jan. 30, 1936, a captain on Jan. 22, 1938 and major on Dec. 29, 1941.

The McCloskey General Hospital has a capacity at present of 1,500 beds, and a second unit is now under construction for an additional 1,500 beds. The following doctors serve as chiefs of services: surgical, Lieut. Col. Foy Roberson; medical, Major Sloan G. Stewart, M. C.; laboratory, Major David M. Earl; laboratory, Major Paul G. F. Schmitt; dental, Lieut. Col. Leslie D. Maurer; nurses, Capt. Zita Callaghan. The hospital buildings are all two-story red brick with green composition roofs. The hospital has many buildings which are joined by covered passageways, so that patients may be moved without exposure to the weather. There are ramps connecting the first and second floors. The hospital has its own laundry, guard house, hospital exchange, post office, commissary, fire department, railroad station and Red Cross building with an auditorium. The McCloskey General Hospital, which admitted its first patient on Oct. 20, 1942, is equipped to handle all types of cases.

ONE THOUSAND MEDICAL ADMINISTRATIVE OFFICERS A MONTH AT CAMP BARKELEY

The first of the new semimonthly groups to complete the medical administrative officer training at the Medical Replacement Training Center Officer Candidate School, Camp Barkeley, Texas, graduated on January 13, and following a ten-day leave the members of the graduating class reported to their station assignments. The medical administrative officers are selected mostly from the medical department and after their graduation and commissioning take over the duties of supply training, personnel and other administrative work, thus releasing doctors of medicine for medical and surgical work.

The Surgeon General of the Army recently announced that a thousand soldiers will be commissioned at Camp Barkeley each month during 1943. The faculty of this officer candidate

school at this large medical replacement training center consists of Brig. Gen. Roy C. Hefebower, commandant; Col. George E. Armstrong, assistant commandant; Lieut. Col. Charles I. Driscoll, executive officer; and Lieut. Clement A. Studebaker, secretary, and the following directors of departments: Capt. Miles G. Bell, administration; First Lieut. James A. Kennedy, logistics; Major Francis B. Elder, sanitation; Major Wayne A. Starkey, tactics; Major August H. Groe, drill, training; Major Joseph J. Wampler, chemical warfare liaison officer; and Lieut. Col. Harold C. Washburn, infantry liaison officer.

The officers and enlisted men at this medical replacement training center to date have purchased war bonds with a maturity value of \$1,938,800. According to the public relations officer, these soldiers are making doubly sure that when it comes their turn to enter the combat zones they will have enough equipment to do the job.

MICHIGAN TO TRAIN SPECIALISTS FOR THE ARMY

The War Department, Washington, D. C., has selected the University of Michigan as one of twelve universities in the country to present a special series of intensive courses in the medical and surgical specialties for the training of army medical and dental officers. According to the *Detroit Free Press*, the special courses at Ann Arbor will vary from six to twelve weeks and succeeding courses will be given at least until June 30, each course being given to from two hundred to four hundred officers, none of whom will be over 50 years of age. Special emphasis will be placed on courses in tropical medicine. Only those will be selected to enter the special courses in surgery who have had a minimum of twelve months' full-time practical training in general surgery.

BRIGADIER GENERAL GRANT VISITS AFRICA

Brig. Gen. David W. Grant, air surgeon, U. S. Army, recently returned from the front theater of operations in Africa where he visited the medical installations of the Army Air Corps. General Grant gave an address at the Medical Field Service School at Carlisle Barracks, January 9, based on his African experience, pointing out the difficulties surmounted by the air corps in establishing medical installations for air evacuation and emphasizing the efforts of the U. S. Army in Africa in preventive medicine and sanitation.

BRITAIN TURNS OVER FIVE HOSPITALS TO UNITED STATES FORCES

Five new hospitals, fully equipped by Great Britain, have been turned over to the United States forces, according to an announcement by the minister of health, Ernest Brown, on Dec. 17, 1942, who at the same time announced that the Canadian forces had been given the use of eight hospitals.

ARMY PERSONAL

Major E. A. Zimmermann, M. C., has been promoted to lieutenant colonel. Colonel Zimmermann was in practice in Dayton, Ohio, before entering the army and since November 1941 has been assigned to the Medical Replacement Training Center at Camp Barkeley, Texas. He is a graduate of St. Louis University Medical School and entered the army two years ago as a first lieutenant.

CIVILIAN DEFENSE

CARE AND DISTRIBUTION OF
GAS MASKS

The Office of Civilian Defense, Washington, D C, issued on January 20 Operations Letter 106, for the special attention of states and communities to which gas masks have been allocated

Noncombatant masks are now being shipped from manufacturers and U S Office of Civilian Defense supply depots to communities which have received allocations of masks and have returned properly executed, OCD form No 501 These will be in assorted sizes

Valuable and critical materials are used in the manufacture of gas masks Hence care must be exercised in their handling, distribution and storage in order that the usefulness of the present limited supply may be preserved

It is recommended that 5 per cent of the masks other than those designated for training purposes be held in reserve by the local property officer, that defective masks and those with exhausted canisters be replaced from this reserve and that the remainder, other than those designated for training purposes, be distributed to the protective services in communities in accordance with 'Regulations No 1 Governing Loans of Equipment and Supplies to Civil Authorities' (paragraph 7c)

It is recommended that about 20 per cent of the number allocated to each service be stored by that service in places readily available, as for example police stations, fire stations, sector wardens' posts, hospital and casualty stations serving as assembly points for medical teams rescue depots, public works and public utilities warehouses Storage must be in a cool dry place, and masks should be kept from contact with sunlight, oils or corrosive liquids and vapors This increment of masks should be held as a reserve and should not be assigned to individuals It is important that this reserve be decentralized as a safeguard against fire or bombing and also to permit rapid distribution in case of an emergency

The remaining 80 per cent allocated to the services may be issued to individuals in the services but should not be carried by them during their daily activities These masks should be

kept at the posts where the individuals will assemble during drills or enemy action Under no circumstances should masks be assigned to individuals before they have received training in their use and care, including proper storage

The commander of the local U S Citizens Defense Corps, through his senior gas officer, should immediately arrange a gas mask training program for those to whom masks are to be issued If no senior gas officer has been appointed, steps should be taken to appoint one in accordance with Operations Letters 42 and 91

In the training program the commander and senior gas officer of the local U S Citizens Defense Corps should utilize the services of individuals in the community who have attended the War Department civilian protection schools If there are no qualified individuals, assistance should be sought from the state gas consultant, who may request aid from the regional director of the U S Office of Civilian Defense

Repair of masks is not to be attempted locally except in case of extreme necessity Defective masks or those with exhausted canisters should be collected by the local property officer and returned, preferably in lots of twenty or more, to the nearest U S Office of Civilian Defense supply depot for repair and replacement

Salt Lake City 341 Pierpont Avenue.

Chicago 1750 Wrightwood Avenue

Fitchburg Mass Willow Street

Hannover Pa

Birmingham Ala 503 South Twenty Second Street (Long Furniture Manufacturing Company)

When a local property officer has masks which he wishes to return, he should so notify the nearest depot commander, who will then send shipping instructions and a government bill of lading which will authorize the transportation of the damaged masks without expense to the locality

After use, masks should not be worn by another individual without proper sterilization Instructions for sterilization are given in Office of Civilian Defense publication "Protection Against Gas"

MISCELLANEOUS

COMMITTEES ON WAR PARTICIPATION

In a recent conference of the War Participation Committee of the American Medical Association it was urgently suggested that all state associations create similar committees, so that these committees may supplement the existing committees on medical preparedness, even without any change in their personnel In this connection the chairman of the committee, Dr Walter F Donaldson, Pittsburgh, points out that the functions of this committee described by the House of Delegates of the American Medical Association which met in 1942 are as follows

'It should feel free to express comments and criticism of policies relating to the participation of the medical profession in the war effort

"Without authority to act, only to advise, it becomes a committee to express the views of the medical profession on such proposals as are made which may have a direct bearing on the principles which the American Medical Association regards as fundamental in the provision of good medical service"

RUSSIA EXPRESSES GRATITUDE FOR AID

Soviet Ambassador Maxim Litvinov said at the annual meeting of the board of directors of Russian War Relief, Inc, in Washington, D C, 'I am authorized and greatly privileged to express on behalf of the Soviet Government the Red Army and all Soviet people their deep gratitude to Russian War Relief, to its board, to all working in the organization and to all contributors It is hardly possible to put into words the gratitude to America felt by wounded Red Army men receiving anesthetics during surgical operations, by those who, thanks to other medicaments from this country, have received alleviation from pain or a cure of their ills or by those who have kept them-

selves warm in American clothes on the field of battle and in the trenches during freezing winter days and nights The evacuated citizen too has been warmed, body and soul, by the receipt of winter clothing Thanks to timely medical aid, many Red Army men have had their time in the hospital shortened and been enabled to return to the front, so that Russian War Relief may be said to have influenced the numerical strength of our forces and thus to a certain extent to have done its bit for the victories of the Red Army"

Litvinov especially stressed the value to international friendship of the work of Russian War Relief He concluded by expressing confidence "that the friends of Russian War Relief will not weary of well doing and that the next report will rejoice our hearts with no less satisfactory, if not with still greater, results"

Edward C Carter, president of Russian War Relief, Inc, announced that since its inception in the fall of 1941 it had raised by Dec 31, 1942 in contributions in cash, in kind and in collectible pledges a total of \$9,342,204 The total of relief goods shipped and in purchase commitments as of December 31 was \$5,244,000, of which 78 per cent was for medical and surgical supplies, 15 per cent for clothing, knitgoods and blankets, 6 per cent for foodstuffs and seeds, and 1 per cent for miscellaneous items Carter said that relief needs in Russia during 1943 are expected to be far greater than in 1942 Success of the 1942 campaign, Carter said, was due to the wide support given Russian War Relief by labor, nationality, fraternal, youth and religious groups

Among others who attended the luncheon, in addition to board members, were Mrs Ivy Litvinov, English born wife of the Soviet ambassador, and Mrs J Borden Harriman, former U S minister to Norway

**DIVISION OF MEDICAL SCIENCE OF THE
NATIONAL RESEARCH COUNCIL
APPOINTS CONSULTANT
GROUP ON MALARIA**

The Division of Medical Sciences of the National Research Council has established a special Subcommittee on Coordination of Malarial Studies including

DR FREDERICK M HANES, Chairman
DR W M CLARK
DR E K MARSHALL JR
DR JAMES A SHANNON
DR HENRY MELENEY
DR O H PERRY PEPPER (ex officio)
DR CHESTER S KEEFER (ex officio)

Under this committee there are panels concerned with chemistry of antimalarials, clinical testing of antimalarials, pharmacology of antimalarials and a special group which is concerned with new investigations on atabrine. The groups established include

Chemistry of Antimalarials (under Division of Chemistry)

DR W M CLARK, Chairman
DR N L DRAKE
DR ROBERT ELDERFIELD
DR E K MARSHALL JR
DR RALPH L SHRINER
DR LYNDON SMALL
DR FREDERICK Y WISELOGLE

Clinical Testing of Antimalarials

DR JAMES A SHANNON, Chairman
DR FRANCIS G BLAKE
DR MARK F BOYD
DR ROBERT B WATSON
DR W BARRY WOOD JR
DR FREDERICK M HANES (ex officio)
DR CHESTER S KEEFER (ex officio)
DR O H PERRY PEPPER (ex officio)

Pharmacology of Antimalarials

DR E K MARSHALL JR, Chairman
DR L T COGGESHALL
DR E M K GEILING
DR HANS MOLITOR
DR W H TALIAFERRO

Conference Committee on Atabrine

DR JAMES A SHANNON, Chairman
DR W M CLARK
DR E K MARSHALL JR
DR HANS MOLITOR
DR L F SMALL, liaison (from U S P H S)

**FURTHER CONSERVATION OF
CINCHONA BARK**

The Office of War Information announced on January 9 that cinchona bark, the source of quinine, and its derivatives are to be further conserved for direct antimalarial use by order M-131 as amended by the director general for operations. The order also limits the use of quinine itself to antimalarials and eliminates the provision in the original order which allowed the use of quinine in the manufacture of quinine and urea hydrochloride and in quinine hydrochloride and urethane. It can be used only for the manufacture of totaquine and certain quinine salts—the sulfate, hydrochloride and dihydrochloride. The dihydrochloride is for intravenous use, and the three quinine salts allowed are needed by the United States Army and Navy.

In addition to the requirement that quinine be used only as an antimalarial, the order requires that it be used only in ampule form uncombined with ingredients other than the necessary solvent and preservative or in powder, 5 grain tablet or 5 grain capsule form, uncombined with ingredients other than necessary fillers and excipients. However, licensed pharmacists may compound quinine in any form on individual prescriptions written by licensed physicians for quinine as an antimalarial agent. Existing stocks of quinine and urea hydrochloride and

of quinine and urethane may be used under the provisions of the order.

Quinine is defined as meaning quinine alkaloid extracted from cinchona bark and the quinine salts derived from quinine alkaloid. Totaquine is defined as a mixture of alkaloids extracted from the bark of cinchona trees the mixture to conform to the standards of the United States Pharmacopeia.

Totaquine, which is considered as valuable as quinine in the treatment of malaria, came into use as a result of experiences gained in India and the Philippines where low grade barks less rich in quinine were found to yield a combination of alkaloids satisfactory for the treatment of malaria.

Certificates are to be filed with the seller or supplier that quinine or totaquine is to be used as an antimalarial agent and that the cinchona bark is to be used for the primary manufacture of quinine or totaquine. This order M 131 as amended in no way changes the restrictions of order M 131-A applying to cinchonine, cinchonidine and quinidine.

LOS ANGELES TO ISSUE FOOD ON PRESCRIPTION FOR SPECIAL DIETS

In accordance with plans made on January 4 at a meeting of the Los Angeles City and County defense council, and the necessity for helping thousands of persons who for reasons of health are on strict diets, it was agreed, in view of the rationing of foods, that certain foods would be provided to such persons on physicians' prescriptions. The city health officer, Dr George Uhl, said that the health authorities have been besieged with pleas from persons who have been unable to obtain the foods needed in their special diets. Under the plan agreed on, a doctor will be able to write a prescription for example for a pound of butter or a dozen eggs or anything else that may be included in the special diet. The plan will operate on a voluntary basis for the present and is expected in view of the cooperative spirit of the merchants and jobbers to have widespread acceptance.

**MEDICAL AND SURGICAL RELIEF
COMMITTEE**

At the annual meeting of the Medical and Surgical Relief Committee of America at its headquarters 420 Lexington Avenue, New York City, in January the executive chairman, Mrs Huttleston Rogers, announced that more than \$30,000 worth of supplies has been furnished during the last year to army air stations, to civil air patrol stations and to the coast guard and amphibious forces of the U S Navy, bringing the total value of the shipments of the Medical and Surgical Relief Committee up to nearly \$500,000. In addition to America's armed forces, supplies were sent also to German prison camps through the International Red Cross, to hospitals and welfare groups in the United States and Alaska and to African missions. Among the supplies sent out in the last year were two hundred and forty-eight complete physician's emergency medical field sets and large quantities of instruments, surgical dressings, sulfonamide compounds, concentrated foods and vitamins.

REHABILITATION OF SELECTEES

Ninety-nine patients with hernia referred to the Illinois State Department of Public Welfare by the Selective Service System were cured and made fit for military service in the last six months, according to a report by the Illinois State Welfare Director submitted to Governor Green. Twenty-five were treated by local or staff physicians and 74 submitted to an operation by the chief surgeon of the Department of Public Welfare, Dr Frederick Gruneck of Chicago. All these men were rehabilitated without charge in state hospitals.

OATH TAKEN BY ALIENS

The director of civilian defense, James M Landis, Washington, D C, on January 7 issued Amendment No 5 to Regulations No 3 of the Office of Civilian Defense, effective immediately. The amendment adds to section 9 (a) the following: "The oath taken by each alien appointed to membership in the Defense Corps may omit the first two clauses of the form hereinbefore set forth."

ORGANIZATION SECTION

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Bills Introduced—S 454, introduced by Senator Langer, North Dakota, proposes to prohibit experiments on living dogs in the District of Columbia. H R 1457, introduced by Representative Randolph West Virginia, proposes to amend the healing arts practice act of the District of Columbia so as to provide for the issuance of temporary permits to practice the healing art

MEDICAL BILLS IN CONGRESS

Bills Introduced—S 227 introduced by Senator Clark, Missouri, proposes to amend paragraph IX of Veterans' Regulation No. 10 so as to define misconduct for compensation and pension purposes as limited to felonious misconduct. S 400, introduced by Senator Thomas, Utah, provides for the organization and functions of the United States Public Health Service. S 450 introduced by Senator Pepper, Florida provides benefits for the injury, death, disability or enemy detention of civilians and for the prevention and relief of civilian distress arising out of the present war. S Res 74 submitted by Senator Pepper, Florida, proposes to authorize the Committee on Education and Labor or any subcommittee thereof to make a full and complete study and investigation of the manpower resources of the United States with particular reference to housing, health, education, technical training and civilian mobilization and morale. S Con Res 4 submitted by Senator Wiley, Wisconsin, proposes to create a joint committee on social security, composed of designated members of the Committee on Finance of the Senate and of the House Committee on Ways and Means. This joint committee will be authorized to investigate with respect to the need for and advisability of modification or enlargement of the present social security program and to consider any proposals submitted to the Congress in connection therewith. S 345 introduced by Senator Murdock, Utah, for himself and Senator Gillette, Iowa, proposes to authorize chiropractors to treat beneficiaries of the United States Employees' Compensation Act. S 463, introduced by Senator Downey, California, proposes to confer on certain persons who served in a civilian capacity under the jurisdiction of the Quartermaster General during the war with Spain, the Philippine Insurrection or the China Relief Expedition the benefits of hospitalization and the privileges of the soldiers' homes. H R 1286, introduced by Representative Izac, California, proposes to amend the Social Security Act so as to provide benefits to persons permanently crippled to a degree such that they are not able to engage in a gainful occupation. H R 1297, introduced by Representative Mott, Oregon, proposes to authorize the Director of the Census to issue certifications of birth records. H R 1298, introduced by Representative Norrell, Arkansas, provides for identification buttons for persons deferred or discharged from or rejected for military or naval service on account of physical defects not due to personal misconduct. H R 1352, introduced by Representative Dielstein, New York, proposes to make it a federal offense to alter the inner surface of the hand for the purpose of preventing identification by the use of fingerprints. H R 1368 introduced by Representative Price, Florida, proposes to authorize an appropriation of \$1,500,000 to construct a 500 bed veterans hospital in Alachua County, Florida. H R 1391, introduced by Representative Lane, Massachusetts, proposes to recognize the high public service rendered by soldiers who volunteered and served in trench fever experiments in the American Expeditionary Forces. H R 1402, introduced by Representative Sparkman, Alabama, and H R 1458, introduced

by Representative Cannon, Florida, propose to direct the Veterans' Administration to provide vocational rehabilitation and assistance in securing suitable employment for service connected disabled veterans in need thereof. H R 1451, introduced by Representative Walter, Pennsylvania, proposes to establish uniform procedure relative to the proof of age, place of birth or proof of death. H R 1453, introduced by Representative Case, South Dakota, provides that veterans of the present war suffering with tuberculous or neuropsychiatric ailments shall receive the same domiciliary or hospital care as veterans of the World War. H R 1259, introduced by Representative Bradley, Michigan, proposes to authorize a federal appropriation of \$700,000 to construct a veterans hospital in or near Gladstone, Mich., with a capacity of 150 beds. H J Res 12, introduced by Representative Keogh, New York, proposes to authorize the President to issue a proclamation designating the week of November 7 as the "National War on Cancer Week" in honor of the birthday of Madame Sklodowska Curie. H J Res 13, introduced by Representative Voorhis, California, proposes to establish the third week of September as National Employ the Physically Handicapped Week. H R 980, introduced by Representative Bates, Kentucky, provides that the Veterans' Administration shall not, in the absence of fraud or clear and unmistakable error, reduce any permanent disability rating. H R 994, introduced by Representative Cunningham, Iowa, provides that in the administration of benefits for veterans the permanent loss of the use of both feet, or both hands, or both eyes, or of one foot and one hand, or one foot and one eye, or one hand and one eye, or the loss of hearing of both ears, or the organic loss of speech, or becoming permanently helpless or permanently bedridden, shall be deemed total permanent disability for insurance purposes. H R 997, introduced by Representative Durham, North Carolina, proposes to amend the National Defense Act of June 3, 1916 by eliminating the Medical Administrative Corps in the Medical Department of the Regular Army and substituting therefor a Pharmacy Corps. H R 1013, introduced (by request) by Representative Lesinski, Michigan, proposes to grant permanent and total disability ratings to disabled men of the Army, Navy, Marine Corps and the Coast Guard suffering from severe industrial inadaptability as a result of active service in the Army, Navy, Marine Corps or the Coast Guard. H R 1029, introduced by Representative Rogers, Massachusetts, provides that notwithstanding any provision of law or veterans' regulation, any World War ex-serviceman shown to have active pulmonary tuberculosis of compensable degree shall be deemed to be totally disabled for purposes of compensation when hospitalized. H R 1108, introduced by Representative Harness, Indiana, provides for the issuance of a certificate of citizenship to any person claiming to be a citizen of the United States at birth in whose case no official record of birth is available. H R 1189, introduced by Representative Rogers, Massachusetts, proposes to direct the Veterans' Administration to provide vocational rehabilitation and assistance in securing suitable employment for service connected disabled veterans in need thereof.

STATE MEDICAL LEGISLATION

Arizona

Bills Introduced—S 30 and H 25 propose the enactment of an occupational disease law and contain a list of thirty five diseases which shall be deemed to be occupational in nature, among which are asbestosis and silicosis. H 4 to amend the pharmacy practice act, proposes to redefine the words "chemicals" and

"medicines" so as not to include "patent" or proprietary medicines in the original package or container and to prohibit the board of pharmacy from issuing permits for the sale of proprietary and "patent" medicines

California

Bills Introduced—S 279, to amend the law relating to the sales tax, proposes to exempt therefrom medicines sold as dietary supplements or adjuncts. S 282 to amend the vehicle code relating to ambulances, proposes that the driver of the ambulance that first arrives at the place where an accident has occurred and who neglects or refuses to care for any injured person or to transport such person to a hospital shall be guilty of a misdemeanor. A 508 to amend the law relating to aid to the aged, proposes that necessary medical or surgical services shall be rendered by the physician or surgeon selected by the aged person. A 528 proposes the creation of a state board of massage to examine and license practitioners of that art. The practice of massage is defined as the use or employment of any method, art or science of administering to the human body for hygienic or therapeutic purposes exclusively, by rubbing, stroking, kneading, tapping or rolling the same manually or the external application of water either natural or mineral, to the human body for the purpose of relieving or alleviating affected parts thereof. Furthermore massage is declared to be distinct from the practice of medicine, surgery, osteopathy, drugless physicians, chiroprody or chiropractic, physiotherapy, and persons duly licensed to practice those professions are excluded from the provision of the proposal. A 530, to amend the labor code relating to the management of hospitals, proposes that any employer who furnishes hospital service shall permit its employees contributing to the maintenance of the service to choose at least a majority of the board of directors or officers in charge of such hospital service. A 573, to amend the business and professions code, proposes to eliminate the issuing of a drugless practitioner's certificate.

Colorado

Bills Introduced—S 135 proposes the enactment of a new public health law.

Connecticut

Bills Introduced—S 253 proposes to authorize the state board of examiners for nursing to issue temporary licenses to properly qualified persons. S 257 to amend the medical practice act, proposes to require applicants for license to show that they have received the degree of doctor of medicine rather than merely a diploma of graduation, from an approved school. S 261, to amend the premarital examination law, proposes to authorize the required certificate to be signed by a physician licensed to practice medicine in the state of Connecticut or any state or territory of the United States or the District of Columbia. S 262 proposes to authorize persons formerly licensed to practice physiotherapy who had retired from active practice or were living outside the state to resume practice in the state by merely notifying the state department of health and paying the required registration fee. S 264 proposes to require physiotherapists to renew their licenses annually. H 470 to amend the uniform state narcotic law, proposes to remove opium, morphine and heroin from the exemption thereof and to make other changes.

Georgia

Bill Introduced—H 29, to amend the law relating to the liens of inn keepers, proposes to include hospitals within such law and to secure by such liens the payment of all sums due for treatment, hospitalization and other accommodations.

Idaho

Bills Introduced—S 14 proposes to exempt all persons serving in the armed forces of the United States from the law requiring persons to procure licenses as a prerequisite to engaging in a trade, occupation or profession and proposes further that such persons shall be in good standing without renewing their licenses during the continuance of such service. S 27 proposes to exempt from the payment of any professional or

occupational license or renewal fee all persons engaged in the military services of the United States and provides that their existing licenses shall remain in good standing for six months following the person's discharge from military service without the necessity of renewal. S 30 proposes to require any physician knowing that a patient treated or examined by him has cancer, carcinoma, lymphoma, sarcoma, leukemia or any form of malignant growth to report the same promptly to the state department of public health. The fine for failing to do this would be \$100 for each offense. H 43 proposes that each applicant for a marriage license shall produce a certificate signed by a licensed physician certifying that the applicant has been thoroughly examined and that he is not infected with syphilis in a communicable stage. The serologic test for syphilis required by the proposal could be made in the laboratory of the department of public health or in a laboratory approved by said department.

Indiana

Bills Introduced—S 69 proposes to authorize any reputable physician duly licensed to practice medicine and surgery or obstetrics in the state of Indiana to practice in any public or private hospital without being required to become a member of the staff of physicians of such hospital subject only to reasonable rules and regulations which shall be the same to all physicians. H 192 proposes to exempt nonprofit corporations formed by hospitals for the purpose of issuing contracts to furnish hospital care to individuals or groups of individuals from the state insurance laws.

Iowa

Bills Introduced—S 36 proposes to prohibit certain types of advertising by persons engaged in prescribing or supplying eyeglasses. S 67 proposes that when a town accepts a gift and the same is used to establish a hospital it shall on direction of the county supervisors furnish care to indigent persons committed to it by the county board at the expense of the county. S 82 and H 126, to amend the income tax law propose to authorize taxpayers to deduct expenses for the medical care of the taxpayer his spouse or a dependent and the term medical care is defined as amounts paid for the diagnosis, cure, mitigation, treatment or prevention of disease or for the purpose of affecting any structure or function of the body.

Kansas

Bills Introduced—S 53 proposes to prohibit children from attending school unless they have been vaccinated against smallpox and immunized against diphtheria. H 91 proposes to authorize the board of medical registration and examination to issue temporary certificates to physicians licensed as such outside the state if they are found qualified to practice in the state during the present war emergency. The holder of such temporary certificate would be privileged, during the term specified, to practice his profession within the state subject to all laws of the state generally applicable to the practice of such profession and subject to such rules, regulations, restrictions and area limitations as the state board of medical registration and examination may impose. H 92 proposes the creation of a state board of consulting psychologists to determine the qualifications of persons desiring to practice such profession and to issue licenses therefor. The term consulting psychologist is not defined by the proposed bill.

Massachusetts

Bill Introduced—H 450 to amend the unemployment security law proposes to authorize payment to persons who leave their employment temporarily or permanently because of illness, disease or state of health requiring or justifying such leaving provided that in case of such illness, disease or state of health the director shall establish rules and regulations for registering and giving notice etc.

Michigan

Bills Introduced—H 59 proposes to prohibit the sale of barbituric acid or any of its derivatives, sulfinilamide and any of its derivatives, chloral hydrate or paraldehyde, except under certain conditions. Licensed physicians, dentists and veteri-

narians could make sales of such substances provided certain record requirements are fulfilled and druggists and pharmacists would be proscribed from selling such substances except on prescription of a licensed physician, dentist or veterinarian. H 62 proposes to require school boards to provide for the annual physical examination of all pupils in said districts.

Minnesota

Bills Introduced—S 108 and H 160, to amend the law relating to the reporting of births occurring in maternity hospitals, propose to require such hospitals to file a written report with the director of social welfare of the birth of any child known or believed to be illegitimate within twenty-four hours after the birth occurs.

Missouri

Bill Introduced—H 85, to amend the Missouri laws relating to the construction of statutes, proposes that the words "physician" and "surgeon" shall be construed to include the practice of any school of medicine recognized by the laws of Missouri, including a practitioner of any osteopathic school of medicine recognized by the laws of Missouri, as being endowed with definite privileges, rights and duties, such as the right to practice as doctors their respective arts of healing by giving physical examinations and by prescribing remedies and treating diseases of the human body and mind and thereby endeavoring to alleviate diseases and pain of any patient, including the privilege, right and duty to practice their respective healing arts in all hospitals or institutions built or maintained by revenue derived from public taxes, to practice as doctors their respective healing arts by rendering public health, public safety and public sanitation services and public precautionary measures sanctioned by any act of congress or sanctioned by any Missouri statute.

Montana

Bill Introduced—S 17 proposes the enactment of a new vital statistics law.

Nebraska

Bills Introduced—Bill No 124, to amend the laws regulating the practice of osteopathy, proposes, among other things, to increase the scope of practice authorized to osteopathic licentiates to include operative surgery with instruments and obstetrics, and the use of antiseptics, anesthetics, narcotics, biologics, analgesics, anodynes, antidotes, serums and vaccines. Bill No 139, to amend the laws regulating the practice of medicine and surgery, proposes, among other things, that (1) persons serving an internship in an accredited hospital shall be exempt from the provisions of the law, (2) osteopathic licentiates shall be exempt from the law unless they represent themselves to be physicians and surgeons or profess or hold themselves out to administer or prescribe drugs in any form or perform operative surgery with instruments or practice obstetrics, (3) chiropractic licentiates shall be exempt from the provisions of the law so long as they confine their practice to the treatment of human ailments by the adjustment by hand of any articulations of the spine, (4) any limited licentiate shall be exempt from the law so long as he confines himself strictly to the field for which he is licensed and does not hold himself out as administering or prescribing drugs in any form or performing operative surgery or practicing obstetrics and (5) an approved medical school may now give the required four courses of lectures of eight months each without the limitation that no two of such courses may be held in one year. The proposed amendment provides merely that no two such courses shall be held concurrently. Bill No 149 to amend the pharmacy law, proposes to exempt pharmacists actively engaged in the military service from payment of the annual renewal license fee.

New Hampshire

Bill Introduced—H 32 proposes enabling legislation for the incorporation of non profit sharing organizations formed for the purpose of establishing, maintaining and operating a nonprofit medical service plan whereby medical service may be provided at the expense of said corporation by physicians to subscribers to said plan under contract entitling such subscribers to certain

medical service. The bill sets forth the form of contract method of having rates and contracts approved, method of financing such plans and certain restrictions, among which is the provision that no medical service corporation shall impose any restrictions on physicians who administer to its subscribers as to methods of diagnosis or treatment. The bill also proposes that no person shall become a participating physician unless he shall be a physician holding a full license to practice medicine in the state of New Hampshire.

New York

Bills Introduced—S 9 proposes the creation of a state board of examiners in optical dispensing and sets forth the qualifications to be required of persons desiring to practice optical dispensing. Provisions are made for the granting of licenses, the annual registration of licenses and the revocation of licenses. Optical dispensing is defined as the filling of prescriptions for lenses and the fitting of the glasses but not to include the right to hold oneself out as being able to examine eyes or to diagnose, treat, correct, relieve, operate or prescribe for any human ailment, deficiency, deformity, disease, injury, pain or physical condition. Furthermore, the bill would provide that nothing in its terms should be construed as a limitation or restriction in any respect on the practice of medicine by duly licensed physicians. Finally, the bill proposes that a legally incorporated optical corporation may operate through duly licensed and registered dispensing opticians while conforming to the provisions of the bill. S 34 and A 58 propose a law for the establishment and administration of a system of health insurance. Among other things the bills propose that every general medical and dental practitioner, duly licensed to practice in the state (without discrimination against any school or mode of practice which is lawful in the state), shall have the right to be included in the list of those furnishing the medical benefits provided. Furthermore, every person entitled to the medical benefits provided by the bill shall have the right to select the general medical practitioner by whom he wishes to be attended and treated. S 72 proposes the enactment of a consumers' protection act regulating the registration, standards, sale and labeling of proprietary products, defined as a food, drug, cosmetic or device in which the distinctive name, formula or composition, and in addition the method of manufacture for a device, is the exclusive property of a proprietor, by reason of a patent, copyright, registration or first general use or otherwise and is not dedicated to free public use. S 206 and A 279 to amend the education law relating to physiotherapists, propose to require physiotherapists to treat only quarantinable diseases under the supervision of a duly licensed physician. Under the present law they may not treat any disease except under the supervision of a duly licensed physician.

North Carolina

Bill Introduced—H 110 proposes to authorize state institutions for the care of the sick, feeble-minded or insane to have performed on persons dying in such institutions a postmortem examination in the laboratories of incorporated medical schools, after securing the written consent of the deceased person's husband or wife or next of kin.

North Dakota

Bill Introduced—S 43, to create a state commission for the survey and control of feeble-minded, proposes, among other things, to prohibit the issuance of marriage licenses to any person whose name appears on the official list of feeble-minded persons.

Ohio

Bill Introduced—H 44 to amend the law relating to sales tax, proposes to exempt therefrom the sale of drugs or medicine, compounded, prepared or sold in accordance with or under a prescription issued by a licensed practitioner of medicine.

Oklahoma

Bills Introduced—H 14 proposes the enactment of a premarital examination law. Persons desiring to be married must obtain a certificate from a duly licensed physician, licensed to practice in Oklahoma, that they have undergone a standard

serologic examination and that in the opinion of the physician they are not infected with syphilis in a communicable stage H 37 proposes that state and local officers, or their authorized deputies who are physicians, be empowered to detain and examine persons suspected of being infected with a venereal disease and authorizes the detention of such persons until the results of an examination are known. The examination must be made by a health officer or, at the option of the person to be examined, by an approved licensed physician. H 38 proposes to amend the law dealing with the duties and powers of the commissioner of health and providing that the terms contagious disease and infectious disease shall include venereal disease. The present law now concerns contagious, infectious and malarial diseases. S 56 proposes to create a separate board of examiners for naturopaths and defines naturopathy as the physiologic and mechanical sciences, such as mechanotherapy, articular manipulation, corrective orthopedic gymnastics, neurotherapy, psychotherapy, hydrotherapy and mineral baths, electrotherapy, thermotherapy, phototherapy, chromotherapy, vibrotherapy, thalamotherapy and dietetics which shall include the use of foods of such biochemical tissue building products and cell salts as are found in the normal body, and the use of vegetable oils and dehydrated and pulverized fruits, flowers, seeds, barks, roots and vegetables uncompounded and in their natural state, and, added to the foregoing definition, would include all methods now in use, as physiotherapy, Indian herb, herb and simple remedy doctoring, physical culture, gynecology [sic], autiochemistry, colonic therapy and scientific massage and such methods as are taught in standard schools of naturopathy. The proposal would further constitute a finding that this definition of naturopathy has been approved by an act of Congress dated Feb 7, 1931. Naturopaths would be required to observe and be subject to all state, county and municipal regulations in regard to the control of contagious and infectious diseases, the reporting of deaths and to all other matters pertaining to the public health, in the same manner as is required of other practitioners.

Oregon

Bills Introduced—S 30 proposes that any person otherwise qualified who is graduated in medicine or surgery from the University of Oregon Medical School and who shall have served at least six months in the armed forces of the United States during the present war and been honorably discharged therefrom shall be granted a license to practice the profession in which he graduated without the necessity of taking an examination. S 31, to amend the medical practice act, proposes to authorize persons whose licenses have been revoked or suspended to practice medicine and surgery pending an appeal from such revocation or suspension order. S 35 to amend the workmen's compensation law, proposes to redefine the phrase "personal injury" so as to mean accidental injury or death arising out of and in the course of employment, and such occupational disease or infection as arises naturally out of such employment or as naturally or unavoidable results from such accidental injury. H 101, to amend the law relating to cosmetic therapy, proposes to proscribe the removal of warts, moles or other blemishes by any electrologist. H 103, to amend the law relating to the examination of handicapped children proposes to authorize examinations of the eyes to be made and that the findings be certified to by qualified and licensed optometrists.

Rhode Island

Bill Passed—S 42 passed the senate on January 28. To amend the basic science law, it proposes to exempt from the operation of the act all persons who had on April 27, 1940 already satisfactorily completed one or more full school years at an approved school.

South Dakota

Bill Introduced—S 10 proposes the repeal of two paragraphs in the existing law relating to the use tax. One of these paragraphs exempts tangible personal property not readily obtainable in South Dakota which is to become a capital asset of any trade, business or profession and the other exempts industrial

materials and equipment which are not readily obtainable in South Dakota.

Bill Passed—H 32 passed the House on January 21. It proposes that osteopaths be required annually to renew their certificates to practice and to submit evidence, at the time of such renewal, of attendance of at least two days at the annual educational program conducted by the South Dakota state osteopathic association the preceding year.

Tennessee

Bills Introduced—S 77 proposes to amend the law prohibiting the hiring of food handlers suffering from venereal diseases by providing that all persons so employed must procure a health certificate, including a Wassermann test signed by a physician licensed to practice in the state of Tennessee, which certificate must be renewed annually. Amendment No 1 to S 85 proposes the enactment of a basic science law requiring persons desiring to be examined for the purpose of obtaining licensure to practice the healing art or any branch thereof to pass an examination in anatomy, physiology, chemistry, bacteriology and pathology. Among other things, the proposal would exempt from the operation of its terms dentists, osteopaths, chiropractors, naturopaths, nurses, midwives, optometrists, chiropodists, barbers, cosmeticians or Christian scientists practicing within the limits of their respective callings and persons specifically permitted by any law to practice any form of the healing art in restricted areas without license, except that chiropractors and osteopaths shall be covered by the law if they possess, prescribe or administer drugs in any form. H 39 proposes that hospitals, clinics, sanitariums, doctors, physicians, surgeons, nurses, pharmacists, undertakers, embalmers or other persons called on to render aid to persons suffering from any wound or other injury inflicted by means of a knife, pistol, gun or other deadly weapon or by other means of violence, or suffering from the effects of poison or suffocation, shall report the same immediately to the chief of police. H 48 proposes to amend the law relating to the release of patients from hospitals for the insane by providing that no person shall be discharged or temporarily released from such hospital without the approval of the court committing such person. The existing law authorizes persons to be released when the superintendent of the institution deems it best and advisable. H 187 proposes to amend the law relating to the control of venereal diseases by requiring physicians who make a diagnosis of, treat or prescribe for a case of venereal disease to report such case immediately to the full time municipal district or county health officer. The bill further proposes to authorize state, district county and municipal health officers to detain and examine persons reasonably suspected of being infected with a venereal disease and to require infected persons to report to a reputable physician or clinic for treatment. H 410 proposes the enactment of a permanent registration and identification law. H 420 proposes to prohibit the sale or advertisement of articles used for the prevention of conception without a license issued by the state board of pharmacy except that this proposal would not apply to physicians and medical practitioners regularly licensed to practice medicine or osteopathy in the state of Tennessee. H 460 to amend the premarital examination law, proposes to authorize the required serologic examination to be on forms prepared, approved and distributed by the departments of public health of other states or by the United States Army, Navy, Marine Corps and Public Health Service. The present law restricts such examinations to approved laboratories in the state.

Bills Passed—H 129 passed the House on January 20. The bill proposes the creation of a state board of naturopathic examiners who will be authorized to issue themselves license as naturopathic physicians. Naturopathy means according to this proposal, nature cure or health by natural methods and is further defined as the prevention, diagnosis and treatment of human injuries, ailments and diseases by means of any one or more of the psychologic, physical or mechanical, chemical or material forces or agencies of nature. Such naturopathic licentiates, however, are proscribed from performing any surgical work other than minor matters.

narians could make sales of such substances provided certain record requirements are fulfilled and druggists and pharmacists would be proscribed from selling such substances except on prescription of a licensed physician, dentist or veterinarian. H 62 proposes to require school boards to provide for the annual physical examination of all pupils in said districts.

Minnesota

Bills Introduced—S 108 and H 160, to amend the law relating to the reporting of births occurring in maternity hospitals, propose to require such hospitals to file a written report with the director of social welfare of the birth of any child known or believed to be illegitimate within twenty-four hours after the birth occurs.

Missouri

Bill Introduced—H 85, to amend the Missouri laws relating to the construction of statutes, proposes that the words "physician" and "surgeon" shall be construed to include the practice of any school of medicine recognized by the laws of Missouri, including a practitioner of any osteopathic school of medicine recognized by the laws of Missouri, as being endowed with definite privileges, rights and duties, such as the right to practice as doctors their respective arts of healing by giving physical examinations and by prescribing remedies and treating diseases of the human body and mind and thereby endeavoring to alleviate diseases and pain of any patient, including the privilege, right and duty to practice their respective healing arts in all hospitals or institutions built or maintained by revenue derived from public taxes, to practice as doctors their respective healing arts by rendering public health, public safety and public sanitation services and public precautionary measures sanctioned by any act of congress or sanctioned by any Missouri statute.

Montana

Bill Introduced—S 17 proposes the enactment of a new vital statistics law.

Nebraska

Bills Introduced—Bill No 124, to amend the laws regulating the practice of osteopathy, proposes, among other things, to increase the scope of practice authorized to osteopathic licentiates to include operative surgery with instruments and obstetrics, and the use of antiseptics, anesthetics, narcotics, biologics, analgesics, anodynes, antidotes, serums and vaccines. Bill No 139, to amend the laws regulating the practice of medicine and surgery, proposes, among other things, that (1) persons serving an internship in an accredited hospital shall be exempt from the provisions of the law, (2) osteopathic licentiates shall be exempt from the law unless they represent themselves to be physicians and surgeons or profess or hold themselves out to administer or prescribe drugs in any form or perform operative surgery with instruments or practice obstetrics, (3) chiropractic licentiates shall be exempt from the provisions of the law so long as they confine their practice to the treatment of human ailments by the adjustment by hand of any articulations of the spine, (4) any limited licentiate shall be exempt from the law so long as he confines himself strictly to the field for which he is licensed and does not hold himself out as administering or prescribing drugs in any form or performing operative surgery or practicing obstetrics and (5) an approved medical school may now give the required four courses of lectures of eight months each without the limitation that no two of such courses may be held in one year. The proposed amendment provides merely that no two such courses shall be held concurrently. Bill No 149 to amend the pharmacy law proposes to exempt pharmacists actively engaged in the military service from payment of the annual renewal license fee.

New Hampshire

Bill Introduced—H 32 proposes enabling legislation for the incorporation of non-profit sharing organizations formed for the purpose of establishing, maintaining and operating a nonprofit medical service plan whereby medical service may be provided at the expense of said corporation by physicians to subscribers to said plan under contract entitling such subscribers to certain

medical service. The bill sets forth the form of contract, method of having rates and contracts approved, method of financing such plans and certain restrictions, among which is the provision that no medical service corporation shall impose any restrictions on physicians who administer to its subscribers as to methods of diagnosis or treatment. The bill also proposes that no person shall become a participating physician unless he shall be a physician holding a full license to practice medicine in the state of New Hampshire.

New York

Bills Introduced—S 9 proposes the creation of a state board of examiners in optical dispensing and sets forth the qualifications to be required of persons desiring to practice optical dispensing. Provisions are made for the granting of licenses, the annual registration of licenses and the revocation of licenses. Optical dispensing is defined as the filling of prescriptions for lenses and the fitting of the glasses but not to include the right to hold oneself out as being able to examine eyes or to diagnose, treat, correct, relieve, operate or prescribe for any human ailment, deficiency, deformity, disease, injury, pain or physical condition. Furthermore, the bill would provide that nothing in its terms should be construed as a limitation or restriction in any respect on the practice of medicine by duly licensed physicians. Finally, the bill proposes that a legally incorporated optical corporation may operate through duly licensed and registered dispensing opticians while conforming to the provisions of the bill. S 34 and A 58 propose a law for the establishment and administration of a system of health insurance. Among other things, the bills propose that every general medical and dental practitioner, duly licensed to practice in the state (without discrimination against any school or mode of practice which is lawful in the state), shall have the right to be included in the list of those furnishing the medical benefits provided. Furthermore, every person entitled to the medical benefits provided by the bill shall have the right to select the general medical practitioner by whom he wishes to be attended and treated. S 72 proposes the enactment of a consumers' protection act regulating the registration, standards, sale and labeling of proprietary products, defined as a food, drug, cosmetic or device in which the distinctive name, formula or composition, and in addition the method of manufacture for a device, is the exclusive property of a proprietor, by reason of a patent, copyright, registration or first general use or otherwise and is not dedicated to free public use. S 206 and A 279, to amend the education law relating to physiotherapists, propose to require physiotherapists to treat only quarantenable diseases under the supervision of a duly licensed physician. Under the present law they may not treat any disease except under the supervision of a duly licensed physician.

North Carolina

Bill Introduced—H 110 proposes to authorize state institutions for the care of the sick, feeble-minded or insane to have performed on persons dying in such institutions a postmortem examination in the laboratories of incorporated medical schools, after securing the written consent of the deceased person's husband or wife or next of kin.

North Dakota

Bill Introduced—S 43 to create a state commission for the survey and control of feeble-minded, proposes, among other things, to prohibit the issuance of marriage licenses to any person whose name appears on the official list of feeble-minded persons.

Ohio

Bill Introduced—H 44 to amend the law relating to sales tax, proposes to exempt therefrom the sale of drugs or medicine, compounded, prepared or sold in accordance with or under a prescription issued by a licensed practitioner of medicine.

Oklahoma

Bills Introduced—H 14 proposes the enactment of a premarital examination law. Persons desiring to be married must obtain a certificate from a duly licensed physician, licensed to practice in Oklahoma that they have undergone a standard

serologic examination and that in the opinion of the physician they are not infected with syphilis in a communicable stage H 37 proposes that state and local officers, or their authorized deputies who are physicians be empowered to detain and examine persons suspected of being infected with a venereal disease and authorizes the detention of such persons until the results of an examination are known. The examination must be made by a health officer or, at the option of the person to be examined, by an approved licensed physician. H 38 proposes to amend the law dealing with the duties and powers of the commissioner of health and providing that the terms contagious disease and infectious disease shall include venereal disease. The present law now concerns contagious, infectious and malarial diseases. S 56 proposes to create a separate board of examiners for naturopaths and defines naturopathy as the physiologic and mechanical sciences, such as mechanotherapy, articular manipulation, corrective orthopedic gymnastics, neurotherapy, psychotherapy, hydrotherapy and mineral baths, electrotherapy, thermotherapy, phototherapy, chromotherapy, vibrotherapy, thalamotherapy and dietetics which shall include the use of foods of such biochemical tissue building products and cell salts as are found in the normal body, and the use of vegetable oils and dehydrated and pulverized fruits, flowers, seeds, barks, roots and vegetables uncompounded and in their natural state, and, added to the foregoing definition, would include all methods now in use, as physiotherapy, Indian herb, herb and simple remedy doctoring, physical culture, gynecology [sic], autobiochemistry, colonic therapy and scientific massage and such methods as are taught in standard schools of naturopathy. The proposal would further constitute a finding that this definition of naturopathy has been approved by an act of Congress dated Feb 7, 1931. Naturopaths would be required to observe and be subject to all state, county and municipal regulations in regard to the control of contagious and infectious diseases, the reporting of deaths and to all other matters pertaining to the public health, in the same manner as is required of other practitioners.

Oregon

Bills Introduced—S 30 proposes that any person otherwise qualified who is graduated in medicine or surgery from the University of Oregon Medical School and who shall have served at least six months in the armed forces of the United States during the present war and been honorably discharged therefrom shall be granted a license to practice the profession in which he graduated without the necessity of taking an examination. S 31, to amend the medical practice act, proposes to authorize persons whose licenses have been revoked or suspended to practice medicine and surgery pending an appeal from such revocation or suspension order. S 35, to amend the workmen's compensation law, proposes to redefine the phrase "personal injury" so as to mean accidental injury or death arising out of and in the course of employment, and such occupational disease or infection as arises naturally out of such employment or as naturally or unavoidable results from such accidental injury. H 101, to amend the law relating to cosmetic therapy, proposes to proscribe the removal of warts, moles or other blemishes by any electrologist. H 103, to amend the law relating to the examination of handicapped children, proposes to authorize examinations of the eyes to be made and that the findings be certified to by qualified and licensed optometrists.

Rhode Island

Bill Passed—S 42 passed the senate on January 28. To amend the basic science law, it proposes to exempt from the operation of the act all persons who had on April 27, 1940 already satisfactorily completed one or more full school years at an approved school.

South Dakota

Bill Introduced—S 10 proposes the repeal of two paragraphs in the existing law relating to the use tax. One of these paragraphs exempts tangible personal property not readily obtainable in South Dakota which is to become a capital asset of any trade, business or profession and the other exempts industrial

materials and equipment which are not readily obtainable in South Dakota.

Bill Passed—H 32 passed the House on January 21. It proposes that osteopaths be required annually to renew their certificates to practice and to submit evidence, at the time of such renewal, of attendance of at least two days at the annual educational program conducted by the South Dakota state osteopathic association the preceding year.

Tennessee

Bills Introduced—S 77 proposes to amend the law prohibiting the hiring of food handlers suffering from venereal diseases by providing that all persons so employed must procure a health certificate, including a Wassermann test signed by a physician licensed to practice in the state of Tennessee, which certificate must be renewed annually. Amendment No 1 to S 85 proposes the enactment of a basic science law requiring persons desiring to be examined for the purpose of obtaining licensure to practice the healing art or any branch thereof to pass an examination in anatomy, physiology, chemistry, bacteriology and pathology. Among other things the proposal would exempt from the operation of its terms dentists, osteopaths, chiropractors, naturopaths, nurses, midwives, optometrists, chiropodists, barbers, cosmeticians or Christian scientists practicing within the limits of their respective callings and persons specifically permitted by any law to practice any form of the healing art in restricted areas without license, except that chiropractors and osteopaths shall be covered by the law if they possess, prescribe or administer drugs in any form. H 39 proposes that hospitals, clinics, sanitariums, doctors, physicians, surgeons, nurses, pharmacists, undertakers, embalmers or other persons called on to render aid to persons suffering from any wound or other injury inflicted by means of a knife, pistol gun or other deadly weapon or by other means of violence, or suffering from the effects of poison or suffocation shall report the same immediately to the chief of police. H 48 proposes to amend the law relating to the release of patients from hospitals for the insane by providing that no person shall be discharged or temporarily released from such hospital without the approval of the court committing such person. The existing law authorizes persons to be released when the superintendent of the institution deems it best and advisable. H 187 proposes to amend the law relating to the control of venereal diseases by requiring physicians who make a diagnosis of treat or prescribe for a case of venereal disease to report such case immediately to the full time municipal district or county health officer. The bill further proposes to authorize state, district, county and municipal health officers to detain and examine persons reasonably suspected of being infected with a venereal disease and to require infected persons to report to a reputable physician or clinic for treatment. H 410 proposes the enactment of a permanent registration and identification law. H 420 proposes to prohibit the sale or advertisement of articles used for the prevention of conception without a license issued by the state board of pharmacy except that this proposal would not apply to physicians and medical practitioners regularly licensed to practice medicine or osteopathy in the state of Tennessee. H 460 to amend the promiscuous examination law, proposes to authorize the required serologic examination to be on forms prepared, approved and distributed by the departments of public health of other states or by the United States Army, Navy, Marine Corps and Public Health Service. The present law restricts such examinations to approved laboratories in the state.

Bills Passed—H 129 passed the House on January 20. The bill proposes the creation of a state board of naturopathic examiners who will be authorized to issue themselves licenses as naturopathic physicians. Naturopathy means, according to this proposal, nature cure or health by natural methods and is further defined as the prevention, diagnosis and treatment of human injuries, ailments and diseases by means of any one or more of the psychologic, physical or mechanical, chemical or material forces or agencies of nature. Such naturopathic licentiates, however, are proscribed from performing any surgical work other than minor matters.

Texas

Bill Introduced—H 20 proposes the creation of a separate state board of examiners for chiropractors and defines chiropractic to be the science of analyzing and adjusting the articulations of the human spinal column and its connecting tissues without the use of drugs or surgery.

Washington

Bills Introduced—S 63 proposes the creation of a separate examining board for sanopractic physicians sanopractic being defined as the art and science of applied prophylactic and therapeutic sanitation which enables the physician to direct advise, prescribe or apply food water, roots herbs light, heat exercises active and passive manipulation adjusting tissue vital organs or anatomic structure by manual mechanical or electrical instruments or appliances or other natural agency to assist nature restore a psychologic and physiologic interfunction for the purpose of maintaining a normal state of health in mind and body. Apparently sanopractors would be authorized to practice surgery and obstetrics and to use anesthesia. H 41 proposes to authorize the establishment of emergency health and sanitation areas and sets forth certain regulations applicable to the state board of health in connection therewith.

West Virginia

Bill Introduced—C. C. H. House Bill No 1 (official number not yet received) proposes the enactment of legislation providing for the organization incorporation licensing and operation of nonprofit medical service corporations and hospital service corporations under the supervision and jurisdiction of the insurance commissioner.

Wyoming

Bills Introduced—H 9 to amend the law relating to the practice of chiropractic proposes to require chiropractors at the time of the annual renewal of their license to present evidence that they have attended at least one day of the educational courses given during the prior year by the Wyoming chiropractic association. H 22 to amend the pharmacy laws proposes that a hospital shall not be prohibited from keeping on hand and using professionally drugs medicine or narcotics under the direction of physicians dentists or veterinarians, even though there be no registered pharmacist present.

MEDICAL LEGISLATION PASSED BY THE SEVENTY-SEVENTH CONGRESS

The Seventy-Seventh Congress adjourned on Dec. 16, 1942. Numerous proposals of medical interest had been introduced though perhaps not as many as in preceding congresses. Few measures of major importance in the field of health were enacted other than those associated with the general war effort.

Purity of Insulin—The protection of diabetic patients from impure insulin was assured by the enactment of legislation providing for the distribution of the drug under supervision of the Federal Security Agency. This legislation was necessary because of the expiration of the insulin patent under which the purity and potency of insulin had been regulated.

The May Bill to Control Prostitution—Congress completed action on the May bill prohibiting prostitution within such reasonable distance of military or naval establishments as the Secretaries of War and Navy may determine to be needful to the efficiency, health and welfare of the Army and Navy.

Student Loans—Federal funds to the extent of \$5,000,000 were made available for loans to students pursuing accelerated medical courses and certain other designated technical courses. Likewise additional funds were made available to the United States Public Health Service for the training of nurses to augment the supply of nurses depleted by the demands of the military program.

Osteopaths were persistent in their demands for recognition at the hands of Congress and were successful to the extent that the Surgeon General of the Army was authorized to

appoint osteopaths as interns in army hospitals and to the extent that authorization was included in a bill providing an appropriation for the Navy Department for the use of funds "for the pay of commissioned medical officers who are graduates of reputable schools of osteopathy." Thus far osteopaths have not been appointed as interns in army hospitals nor are osteopaths eligible for commissions in the Medical Corps of the Navy.

The Lanham bill became a law and made considerable federal funds available for the construction in distressed areas of needed public works, including hospitals, health facilities and clinics. Under this legislation, hospital clinic and other health facilities were augmented in many states in areas where existing facilities had proved totally inadequate to serve the influx of population due to defense activities. Additional funds \$4,557,000 too were made available to the Veterans Administration for major reconditioning replacements and new construction of hospitals and domiciliary facilities for veterans.

During the closing days of the Congress legislative action was completed on a Treasury Department initiated measure to regulate the growing of the opium poppy in the United States and to provide for the manufacture of opium from the plants. The growing of the opium poppy particularly in certain Western states has created a distinct problem to prevent the diversion of opium obtainable therefrom into illicit channels. The war too has greatly diminished the sources of supply for opium. The law that was enacted provides a method by which both problems may be handled by the government. Another measure enacted during the last days of the Congress increases the pay and allowances of the Army and Navy Nurse Corps and authorizes the employment by the military establishment of and records a military status to female dietetic and female physical therapy personnel. This law also authorizes the employment of other technical and professional female personnel in categories required for duty outside the continental United States.

The Congress took one more step looking toward the provision of adequate housing for the Army Medical Library when it authorized an additional appropriation for the purchase of a site for the building. Apparently however this urgent project will not be carried to completion until more peaceful times.

As has been previously reported in THE JOURNAL the Soldiers and Sailors Civil Relief Act was variously amended to provide additional relief for persons in military service. Of particular interest to the medical profession is a provision in the amendatory law under which leases for office space entered into by physicians who thereafter enter military service may be canceled.

The new Revenue Act will greatly increase the tax burden of physicians as it will other federal income taxpayers. It does not effect any changes in the deductions that a physician may claim on account of professional activities. It does impose an obligation on physicians who live in their employ persons receiving wages in excess of \$12 a week a duty of withholding the victory tax as explained in detail recently in THE JOURNAL. The new act eliminates an injustice that has obtained for a number of years in the manner in which outstanding accounts on the books of a taxpayer at the time of his death have been treated for income tax purposes. Hereafter such unpaid accounts will not be considered as part of the income of the decedent for the year of death, as has heretofore been the case but will be taxable when paid as a part of the income of the person who receives the money. A provision in the new law also authorizes a taxpayer to deduct amounts expended for medical dental and hospital care to the extent that such expenses exceed 5 per cent of the net income of the taxpayer but not in excess of \$2,500 in case of the head of a family, or \$1,250 in case of other individual taxpayers.

Additional funds were made available to the United States Public Health Service for a continuation of a program to provide reserves of blood plasma in hospitals the reserves being established to meet any wartime contingency caused by enemy action which may necessitate blood transfusion to civilians.

MEDICAL ECONOMIC ABSTRACTS

DISTRIBUTION AND MOVEMENT
OF PHYSICIANS

The directories of the American Medical Association from 1923 to 1938 have been analyzed by the United States Public Health Service¹ to determine the changes in the distribution of physicians within the United States during that period. It was found that 52,000 physicians had left the medical profession and 75,000 had entered it. Nearly 6,000 had both entered and departed from the profession without being included in the totals for either initial or terminal year. Of 94,000 physicians who remained in the directory for the fifteen year period, 13,000 made one or more changes from one state to another.

For an average group of 100 physicians in the 1923 directory, 56 were listed in the same state, 36 had left the profession and 8 had moved to another state by 1938; meanwhile 8 had moved to this state and 51 new registrants had entered the profession. The net effect of these changes reflected an increase of 15.9 per cent in the total number of physicians over the period, an increase almost exactly proportional to the corresponding population increase.

The number of physicians per hundred thousand of population did not change greatly as a whole, nor did the migration of physicians already within the profession greatly change the proportion. The greatest change was due to the number of new physicians settling in the different states. According to the degree of increase or decrease of physicians, the states are divided into three basic groups as follows:

Group A: Arizona, California, Connecticut, Delaware, Florida, Maryland, Massachusetts, Michigan, Minnesota, New Jersey, New York, North Carolina, Rhode Island, Washington, and Wisconsin. Group B: Colorado, District of Columbia, Illinois, Louisiana, Nevada, New Mexico, Ohio, Oregon, Pennsylvania, Texas, Utah, Virginia, and West Virginia. Group C: Alabama, Arkansas, Georgia, Idaho, Indiana, Iowa, Kansas, Kentucky, Maine, Mississippi, Missouri, Montana, Nebraska, New Hampshire, North Dakota, Oklahoma, South Carolina, South Dakota, Tennessee, Vermont, and Wyoming.

1. Mountain J. W., Pennell E. H. and Nicolay Virginia. Location and Movement of Physicians, 1923 and 1938—Turnover as a Factor Affecting State Totals. Pub. Health Rep. 57: 1752 (Nov. 20) 1942.

In group A the number of physicians per hundred thousand increased from 132 to 150. In group B there was a slight decrease from 135 to 131, but in group C there was a significant decrease from 126 to 104. This was brought about by the fact that, of the 100 physicians in group A in 1923, 70 were newly registered physicians while only 40 out of 100 in group B were newly registered physicians and only 31 out of 100 in the states where the largest percentage decrease occurred since 1923.

This difference in the number of physicians newly registered is reflected in existing age differences.

Where the largest gains occurred the median was forty-three years, where physicians increased to a lesser extent the median was forty-nine years, and in states where net losses in physician totals occurred the median was fifty-three years. Accordingly, it is evident that there was a spread of ten years between the median ages for the three groups of states. Such a spread would indicate that those states in which the increment of new physicians was proportionately small are faced with important recruitment problems in the future if the level which even now exists is to be maintained.

While the number of newly registered as well as the total ratio of physicians in the states can be shown to be greatly affected by the ability to purchase medical care, there were nevertheless a number of poorer states and relatively rich ones in each group to indicate that there were other influences at work in determining the distribution of physicians. On the whole, states with high per capita incomes realized much more generous provisions for medical care than did those with low incomes.

It is suggested that the recruitment of new physicians is "related to the extent of physician training facilities in states."

A comparison of the opportunities for internships as shown in the hospital number of *THE JOURNAL* clearly demonstrates that in both wealthy and poor states relatively extensive training opportunities were associated with increased physician totals over the period, whereas states showing decreasing physician totals provided more limited accommodations for the training of interns.

WOMAN'S AUXILIARY

Colorado

The Woman's Auxiliary to the Otero County Medical Society was organized Nov. 13, 1942. Mrs. George W. Miel of Denver, publicity chairman of the Colorado women's auxiliary, and Mrs. Virgil Sells, chairman of the yearbook for the state auxiliary, assisted with the organization. Mrs. R. S. Johnston gave a luncheon to the doctors' wives of La Junta, Air Base, Fort Lyon, and neighboring towns of the valley. Mrs. Johnston was elected president of the Otero County auxiliary. Mrs. J. A. Lawson, Rocky Ford, vice president, and Mrs. A. P. Cash, La Junta, secretary and treasurer. Dr. Johnston, president of the Colorado State Medical Society, attended the meeting.

Illinois

The Woman's Auxiliary to the Chicago Medical Society visited the American Medical Association headquarters Oct. 22, 1942, and made a tour of the building. An extensive program has been carried on by the defense chairman, Mrs. Harry J. Dooley, and her committee. The booth at 30 North Michigan Avenue has been open daily from 10 a. m. until 4 p. m. with auxiliary members in charge. One hundred and sixty-four women have served in this capacity. From February to October more than \$25,000 worth of bonds and stamps were sold.

Mississippi

Thirty members of the auxiliary to the Northeast Mississippi Thirteen Counties Medical Society met at the Tupelo Methodist Church Annex in Tupelo for the December meeting, the president, Mrs. Stanley Hill of Corinth, presiding. Dr. David E. Givton of Blue Mountain College gave an excellent commentary on the war.

New York

Forty members of the Woman's Auxiliary to the Onondaga County Medical Society were luncheon guests of Mrs. Maxwell C. Montgomery at the Rome State School. Miss Inez Stebbins, supervisor of the school colony, traced the growth of the school. Mrs. Andrew Sloan, chairman of the blood plasma bank, gave a report of the clinic which is operating daily at the Utica General Hospital under the direction of Dr. Roscoe C. Borst. The blood plasma bank is a project of the War Council Emergency Committee of which Dr. Fred T. Owens is chairman. The auxiliary began the project in September, 1941, by calling for volunteer donors, and since that time nearly a thousand persons have responded. Committee members are serving daily as registrants at the War Council headquarters and others are making surgical dressings for the blood plasma clinic.

The Oswego County auxiliary members have been busy sponsoring a Navy Relief Horse Show. Mrs. Grove C. Elder was general chairman. The horse show cleared \$1411.99 which was turned over to the Oswego County Navy Relief Society.

West Virginia

Mrs. John P. Helmick of Fairmont, president-elect of the Woman's Auxiliary to the West Virginia State Medical Association, was elected to the same office in the Auxiliary to the Southern Medical Association at the annual meeting recently held in Richmond. At the same session Mrs. Welch England of Parkersburg, immediate past president of the Auxiliary to the West Virginia State Medical Association, was elected a member of the council.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Personal—Dr Andrew M. Hively has been appointed assistant city health officer of Long Beach. He succeeds Dr Frederick G. Hall who had been acting assistant health officer under Dr Frank W. Stewart but who has retired.

State Meeting to Be in Los Angeles—The annual session of the California Medical Association will be held at the Biltmore Hotel, Los Angeles, May 23. The Hotel Del Monte at Del Monte, where the meeting was to be held, has been taken over by the U. S. Navy as a preflight school.

Dr Soley Appointed Head of Pharmacology Division at California—Dr Mayo H. Soley, associate professor of medicine and lecturer in pharmacology, has been appointed chairman of the division of pharmacology at the University of California Medical School, San Francisco. Dr Soley fills the vacancy left when Chauncey D. Leake, Ph.D., resigned to accept the deanship of the University of Texas Medical Branch at Galveston. Dr Soley graduated at Harvard Medical School, Boston, in 1933.

Physician Awarded Distinguished Flying Cross—Lieut. John H. Stark, Los Angeles, a member of the medical corps of the air force since June 1942, has been awarded the Distinguished Flying Cross by General Douglas MacArthur. The *Bulletin* of the Los Angeles County Medical Association reports that Lieutenant Stark, somewhere in the southwestern Pacific, entered the smoldering wreckage of an airplane which had crashed and which contained fused bombs likely to explode and removed injured members of the crew to give them medical treatment.

Dr Tresidder Chosen to Head Stanford University—Dr Donald B. Tresidder has been elected president of Stanford University by action of the board of trustees. He succeeds Dr Ray Lyman Wilbur, who in 1941 reached the retirement age and was appointed chancellor and who since then has been serving as acting president. The appointment will be effective September 1. Dr Tresidder was born in Tipton, Ind., April 7, 1894. He graduated from Stanford University in 1919 and the school of medicine in 1927. He was elected to the board of trustees in December 1939 and became president of the board in May 1942. His father, mother and uncle all were practicing physicians. Dr Tresidder is now president of the Yosemite Park and Curry Company, a position he has held since 1925. He has resigned as president of the board of trustees of Stanford to accept the university presidency. Dr Wilbur, when Dr Tresidder assumes the presidency, will carry on as chancellor, to which position he was elected for life.

GEORGIA

Society News—The Fulton County Medical Society will be addressed February 15, by Drs. Roy R. Krael, Emory University, on 'Highlights of Hematology for 1942' and Paul B. Beeson, Atlanta, 'Review of Acute Respiratory Diseases.'

The Fischer Awards—The L. C. Fischer award of \$100 for the best written paper given before the Fulton County Medical Society during the past year was presented by Dr. Allen H. Bunce, January 4, during the society's thirty-eighth annual meeting to Drs. Joseph Yampolsky and Charles C. Powell for their work on 'Syphilitic Aortitis in a Nine Year Old Child.' A similar prize for the best research work went to Dr. John Ross McCann for his paper on 'Acute Pancreatitis.' All are of Atlanta.

Doctors Day—On March 30 Doctors Day was observed in Georgia in accordance with a resolution that was adopted by the Women's Auxiliary to the Medical Association of Georgia in 1934. A similar resolution was adopted by the National Auxiliary in 1935 and a recommendation made that each state select a day which would celebrate an outstanding medical achievement in that state. Several states have chosen March 30 as their Doctors Days in honor of Georgia which commemorates the day on which Dr. Crawford W. Long 'first used ether anesthesia in surgery.' The Georgia auxiliary published a special tribute by Mrs. Leonard Rush Messengale, Lumpkin chairman of Doctors Day in Georgia.

ILLINOIS

Laboratory Closed—The branch laboratory of the Illinois Department of Public Health at Galesburg was closed on January 30. Calvin Corey, bacteriologist formerly in charge of the Galesburg Laboratory, entered military service on January 14 and has not been replaced. A release from the state department indicated that the present state health budget limitations prevent the department from recruiting civilian bacteriologists qualified to fill highly responsible supervisory positions. Physicians in the Galesburg area wishing to make use of state laboratory services for the examination of various specimens are asked to send such specimens through to the Chicago laboratory of the state health department at 1800 West Illinois Street or to the Springfield Laboratory at 126 North Fifth Street.

Chicago

Kretschmer Memorial Lecture—Dr. Eugene L. Opie, director of the department of pathology, Cornell University Medical College, New York, will deliver the second Edwin R. Kretschmer Memorial Lecture of the Institute of Medicine of Chicago at the Palmer House February 26. His subject will be 'The Experimental Production of Leukemia and Its Significance in Relation to the Human Disease.'

Supreme Court Upholds Sentence of Physician Accused of Abortion—On January 19 the Illinois Supreme Court affirmed the criminal court conviction of Dr. Nathaniel H. Schaffner, who had been charged and found guilty of performing an abortion, newspapers reported. The physician was sentenced to fourteen years in prison. The woman in the case died on July 7, 1942 in Dr. Schaffner's office, it was stated.

Electron Microscope Installed at Institute of Technology—The Illinois Institute of Technology has installed an electron microscope which is said to be the first in the Chicago area. The microscope is in the physics building at the institute. Research work will be carried out under the supervision of James S. Thompson, Ph.D., director of the department of physics. One of the first subjects to be studied will be cancer, which has heretofore occupied the attention of Dr. Thompson.

MAINE

Society News—Dr. Forrest C. Tyson, Augusta, spoke on 'Dementia Precoxa' before the Kennebec County Medical Association at a meeting in Augusta recently. The Penobscot County Medical Association was addressed in Bangor recently by Dr. B. Earl Clarke, Providence, R. I., on 'The History of the Microscope and Early Microscopy.' At a meeting of the Piscataquis County Medical Association in Milo recently Lieut. Allan J. Stinchfield, Skowhegan, M. C. U. S. Army, spoke on 'Chemical Warfare.' Dr. Howard M. Chute, Boston, addressed a recent meeting of the Oxford County Medical Society in Rumford on 'The Problems of Acute Cholecystitis.'

MARYLAND

Industrial Hygiene Laboratory at Johns Hopkins—Announcement is made of the establishment of the army industrial hygiene laboratory at the Johns Hopkins University School of Hygiene and Public Health, Baltimore. The laboratory will operate under the direction of the occupational hygiene branch of the preventive medicine division of the Office of the Surgeon General of the Army. Its function will be to conduct surveys and investigations concerning occupational health hazards in army owned and operated industrial plants, arsenals and depots, making reports on examinations of such gases, fumes, dusts, toxic substances or chemicals as may be collected in army plants.

MASSACHUSETTS

Tufts Alumni Lecture—Comdr. A. Warren Stearns, M. C., U. S. Naval Reserve, on leave of absence as dean of Tufts College Medical School, Boston, will deliver the annual Tufts Alumni Association Lecture at the medical school February 19. His subject will be 'Social Equilibrium.'

Dr. Carpenter Made Director of Nutrition Laboratory at Carnegie Institute—Thorne M. Carpenter, Ph.D., since 1937 acting director of the Nutrition Laboratory of the Carnegie Institution of Washington, Boston, has been appointed director of the laboratory. Dr. Carpenter received his degree of doctor of philosophy at Harvard University in 1915. For a time early in his career Dr. Carpenter was assistant chemist at the Hatch Experimental Station, Massachusetts Agricultural College, and at the Pennsylvania State College Experimental Station. Later he was expert in animal nutrition at the Bureau of Animal Industry, U. S. Department of Agriculture. From 1905 to 1907 he was research chemist of the Carnegie Institute.

tion of Washington, stationed at Wesleyan University, Middletown Conn., and scientific assistant in nutrition investigations for the U S Department of Agriculture. He was also instructor in chemistry at Wesleyan in 1907, when he went to the Nutrition Laboratory, Carnegie Institution, Boston as research chemist. He was president of the American Institute of Nutrition from 1940 to 1941.

Symposium on Aviation Medicine—The department of ophthalmology of Boston City Hospital sponsored a symposium on aviation medicine in compliance with requests from representatives of the medical corps of the United States Army and Navy for the training of future medical officers for services with aviation units. Ross A. McFarland, Ph.D., assistant professor of industrial research in the Fatigue Laboratory, Harvard University, Boston, spoke January 17 on "The Whole of the Medical Program in Civil Aviation" and January 24 on "The Effects of High Altitude in Aviation." On January 31 the speakers were Comdr. A. Warren Stearns, M.C., U.S. Naval Reserve, on "The Application of Psychiatry to the Military Needs" and Lieut. Edward J. Galway, U.S. Naval Reserve, "The Application of Psychology to the Selection and Maintenance of Aircraft Pilots." Others in the series will be Capt. John C. Adams, M.C., U.S. Navy, on "Naval Aviation," Lieut. Comdr. Frank R. Philbrook, M.C., U.S. Naval Reserve "Demonstration of a Naval Flight Physical Examination," Dr. Varaztad H. Kazanjian, Boston, "Early Treatment of Traumatic Injuries of the Face and Jaw," and Dr. Donald Munro, Boston, "Head and Spinal Injuries."

NEW JERSEY

Dr. Franz C. Schmelkes Dies—Franz C. Schmelkes, Ph.D., assistant director of the research department of Wallace and Tiernan Products, Newark, since 1927, died Dec. 11, 1942, aged 43, of angina pectoris. Dr. Schmelkes was born in Prague, Czechoslovakia. He had done considerable research in organic chemistry, sterilization of water and pharmacology.

Personal—William T. Anderson, Jr., Ph.D., since 1923 director of the radiation research laboratory of the Hanovia Chemical and Manufacturing Company, Newark, has been granted a leave of absence to accept a commission as lieutenant in the U.S. Naval Reserve.—Dr. Wells P. Eagleton, Newark, recently received an honorary degree of doctor of science from the University of Newark.

Kenny Treatment Center Opened in Jersey City—The establishment of a school for training physicians, technicians and nurses in the Kenny method for the treatment of infantile paralysis at the Jersey City Medical Center has been announced. The school will open in February under the co-sponsorship of the New York University and the state chapter of the National Foundation for Infantile Paralysis.

Alcoholic Consultation Bureau—The establishment of the Alcoholic Consultation Bureau, Inc., with headquarters at 744 Broad Street, Newark, is announced in the December *Quarterly Journal of Studies on Alcohol*. The bureau is described as an organization specializing in prevention and cure of alcoholism to which a person who cannot control his drinking can go. The staff consists of a psychiatrist, a social worker-psychologist and a lawyer. A nominal fee is charged with no charge to needy persons. The advisory council of the bureau consists of members of committees of the Research Council on Problems of Alcohol and includes Drs. Robert E. Fleming, Boston, Norman H. Jolliffe, New York, Lawrence Kolb, Washington, D.C., Edward A. Strecker, Philadelphia, Leonard V. Harrison, LL.D., Bronxville, N.Y., and Major Merrill Moore, medical corps of the Army.

NEW MEXICO

Public Health Conference—A medical and public health conference was held at Albuquerque on January 18 for the staffs of the local U.S. Indian Medical Service, New Mexico's Third Health District and the New Mexico Department of Public Health with Dr. Ralph B. Snavely, Albuquerque, medical director, district number 3 of the U.S. Indian Service presiding. Dr. John W. Elder, Albuquerque, acting district health officer, opened the meeting and other speakers included Dr. Snavely on "Immunization Procedures," Miss Ester Flynn, R.N., Bernadillo and Miss Gladys Anderson, R.N., "Sulfaguanidine in Treatment of Dysentery," "Nursing Considerations," Dr. Michel Pujon, Albuquerque, "Practical Application of Nutrition Research," and Dr. Sophie B. D. Aberle, Albuquerque, "Nutritional and Vitamin Content of Native Plants." A group of motion pictures on various topics was shown.

NEW YORK

Utica Hospital Observes Hundredth Anniversary—On January 16 appropriate ceremonies marked the hundredth anniversary of the Utica State Hospital, Utica. The hospital was opened as the New York Lunatic Asylum on Jan. 16, 1842. Among the speakers at the recent celebration were Drs. William J. Tiffany, Albany, commissioner of the New York State Department of Mental Hygiene, Arthur H. Ruggles, Providence, R.I., president of the American Psychiatric Association, Willis E. Merriman, Utica, superintendent of the hospital, Richard H. Hutchings, Utica, former superintendent of the hospital, Samuel W. Hamilton, Washington, D.C., mental hospital adviser of the U.S. Public Health Service, and Mr. Homer Folks, New York, secretary of the State Charities Aid Association and chairman of the state's temporary commission on state hospital problems. A short history of the hospital was compiled as a booklet to mark the occasion.

New York City

Dr. Bela Schick Honored—A dinner was held at the Hotel Astor, Dec. 11, 1942, in honor of Dr. Bela Schick and for the Russian War Relief. The speakers at the dinner included Dr. Henry E. Sigerist, director of the Institute of the History of Medicine at Johns Hopkins University, Baltimore, and Major George Fielding Eliot, author and military critic.

The Biggs Memorial Lecture—Lieut. Col. Paul F. Russell, Army of the United States, chief of the Tropical Disease and Malaria Control Section, Division of Preventive Medicine, Office of the Surgeon General, Washington, D.C., will deliver the annual Hermann M. Biggs Memorial Lecture on April 1 at the New York Academy of Medicine. His subject will be "Malaria and Its Influence on World Health."

Information and Counseling Service—On January 25 the mayor's committee on wartime care of children held a special program to open the first information and counseling service in the Harlem Health Center. The service will be available to working mothers six days and two evenings a week. Among the speakers were Mayor La Guardia and acting welfare commissioner Leo Arnstein, chairman of the committee. Special tribute was paid to the late William Hodson, who was killed in an airplane crash, January 15, while on a leave of absence from his position as commissioner of public welfare to carry out a special mission for Herbert H. Lehman, federal director of foreign relief and rehabilitation.

NORTH CAROLINA

Physician Chosen as Raleigh's Outstanding Citizen—Dr. Alexander Webb, Jr., on January 22 was presented with a gold key by the Junior Chamber of Commerce of Raleigh for his selection as "Raleigh's outstanding young citizen of 1942." The presentation of the key was made at a banquet at the Hotel Carolina. Dr. Webb was selected by the award committee in recognition of his leadership and contributions of service in organization of the local medical unit of civilian defense and other activities in civilian defense and civic life. Dr. Webb is a native of Raleigh. He graduated at the University of North Carolina and in 1937 at Harvard Medical School, Boston. He has been associate chairman of the emergency medical unit of the Raleigh Citizens Defense Corps since 1941.

OHIO

Personal—Dr. Virginia B. Hickerson has been appointed pediatrics coordinator for the Anti-Tuberculosis League of Cincinnati and Hamilton County, succeeding Dr. Barbara A. Hewell.—Dr. Joseph B. Stocklen, Cleveland, medical director of the Cuyahoga County Tuberculosis Dispensary, has been appointed controller of tuberculosis for Cuyahoga County. With the appointment the case finding program, nursing activities, clinics, admissions, hospitalization, record keeping and rehabilitation services in the entire county have been placed under one administrative officer.

Chemical Warfare Course—Western Reserve University School of Medicine, Cleveland, and the Office of Civilian Defense cooperated in January in a chemical warfare course for physicians, hospital administrators and nurse executives. Instructors were:

Dr. Joseph Seifter, assistant professor of pharmacology
Dr. Harold D. Green, associate professor of physiology
Dr. Walter H. Pritchard, instructor in medicine
Dr. John A. S. Gammel, assistant clinical professor of dermatology and syphilology
Dr. John W. Holloway, assistant clinical professor of surgery
Dr. Robert M. Stecher, assistant clinical professor of medicine

Two programs were offered, one for the east side of Cuyahoga County, Lake Ashabula and Geauga counties and the other for the western section of Cuyahoga County, Lorain and Erie counties.

OREGON

"Be Kind to Doctors Week"—Portland observed "Be Kind to Doctors Week" Dec 13-19, 1942, according to *Northwest Medicine*. Newspaper and radio publicity was used which urged the public to cooperate by calling physicians early in illness to avoid night calls and by going to the office when possible. The public was also asked to help the hospitals by making shorter visiting hours, taking fewer bouquets to patients and helping feed or wait on patients to relieve the nurses.

PENNSYLVANIA

Smallpox in Pennsylvania—On January 16 the *Science News Letter* reported that 52 smallpox cases were recorded in latest returns to the U. S. Public Health Service for the entire state of Pennsylvania. Seventeen cases were recorded for the rest of the nation, the group being scattered over five different states.

Philadelphia

Annual Postgraduate Institute—"Management of Emergencies" will be the theme of the annual postgraduate institute of the Philadelphia County Medical Society to be held at the Benjamin Franklin Hotel, May 11-14.

Dr. Opie Temporary Director of Phipps Laboratories—Dr. Eugene L. Opie, New York, has been acting as temporary director of the laboratories of Henry Phipps Institute since Dr. Esmond R. Long entered the army medical corps as chief of the division of tuberculosis. Dr. Opie has spent at least one day each week at the Phipps Institute as consultant and supervisor of research. Dr. Opie has also been directing the work of the department of pathology at Cornell University Medical College, N. Y., from which he once retired during the absence of Dr. William Dock, who entered the army.

Pittsburgh

Society News—Dr. Robert C. Grauer addressed the Allegheny County Medical Society January 19, on "The Evaluation and Management of the Endocrine Patient" and Dr. Ernest P. McCullagh, Cleveland, "Male Sex Hormone". —Drs. Wendell B. Gordon and Floyd H. Bragdon discussed "The Basis of Electrocardiographic Diagnosis" and "Low Back Pain from Neurosurgical Viewpoint" respectively, before the Pittsburgh Academy of Medicine, January 12.

WASHINGTON

Changes in Health Officers—Dr. Elizabeth Gunn McCann Omak has been appointed health officer of Okanogan County to continue the unexpired term of Dr. Glenn L. Stevens. Okanogan, who has entered military service. —Dr. Frederick M. Petrie has been appointed health officer of Tappanish, succeeding Dr. Angus Meagher, who has gone into military service.

Dr. Kahl Named Assistant Director of Health—Dr. John A. Kahl, district health officer with headquarters at Walla Walla, has resigned to become assistant director of health of Washington, newspapers reported on December 29. The district of which he has been head includes Walla Walla, Benton and Franklin counties. At one time Dr. Kahl had served as director of local health for the state department of health and as health officer of Clark County.

Society News—Dr. William K. Livingston, Portland, Ore., addressed the Walla Walla Valley Medical Society in Walla Walla recently on "Vascular Diseases". The society has also been addressed recently by Dr. Lester J. Palmer, Seattle, on "The Significance of Glycosuria" and Dr. Paul G. Flathow, Seattle, on "Herniation of the Intervertebral Disk versus Spinal Injury and Low Back Pains". —The King County Medical Society was addressed in Seattle, February 1, by Dr. Byron F. Francis, Seattle, on "Influenza Pneumonia" and Lieut. Comdr. Winfred H. Bucermann, M. C. U. S. Navy, Bremerton, "Treatment of Air Raid Casualties at Site of Incident".

Largest Indian Hospital Completed—The newly completed Cushman Hospital adjacent to the city of Tacoma is the largest Indian institution in the country according to *Northwest Medicine*. Built by the U. S. Department of the Interior as an enlargement of the old hospital, the new unit is six stories high and contains 350 beds with all facilities for surgical, medical, obstetric and tuberculous patients and with x-ray equipment. Patients will be received from Indian tribes from Washington, Oregon, Idaho, Montana, northern California and Alaska. Formerly the institution was a combination hospital and Indian school for reservations covering the major part of Pierce and King counties. The Cushman Hospital now covers 38 acres and fulfills terms of Indian treaty rights dating back to 1855. Dr. Jesse H. Hendry, Tacoma, is the staff superintendent.

GENERAL

Board Examinations in Otolaryngology—The American Board of Otolaryngology will hold its next examination in New York at the Waldorf-Astoria Hotel and the New York Eye and Ear Infirmary June 3-5. Dr. Dean M. Lierle, University Hospitals, Iowa City, is the secretary-treasurer of the board.

Pathologists Postpone Meeting—The American Association of Pathologists and Bacteriologists has canceled its annual meeting scheduled to be held at the University of Chicago, April 1-2. The council of the association will meet early in April to transact the necessary business of the association. Nominations for membership, together with supporting data and not less than two letters of recommendation, should be in the secretary's office not later than April 1. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, is the secretary.

Annual Dinner of Planned Parenthood Federation—The annual meeting of the Planned Parenthood Federation of America was held at the Waldorf-Astoria, New York, January 28-29. Various work shop conferences for state leagues made up the program for the first day. One session of the second day was devoted to a panel discussion on "Planned Parenthood in Wartime". At the annual dinner "Family Health in America" was discussed by Earnest Albert Hooton, Ph.D., professor of anthropology, Harvard University, Boston, and Charles P. Taft, LL.D., assistant federal director of Defense Health and Welfare Services, Washington, D. C. Albert D. Lasker, New York, retired head of the former Lord & Thomas Advertising Agency, gave \$50,000 to the federation. It was announced on January 20.

American Orthopsychiatric Association—The twentieth annual meeting of the American Orthopsychiatric Association will be held at the Hotel Pennsylvania, New York, February 22-24. A general session on "Problems of a Wartime Society" will open the session with Dr. Franz G. Alexander, Chicago, Gardner Murphy, Ph.D., New York, and G. Howland Shaw, assistant secretary of state, Washington, D. C., as the speakers. This theme will also close the program. There will be a special section meeting on "The Military Scene and the Individual" and one on the "Psychology of Preadolescent Children in Wartime". Round table discussions will be held on "Treatment of Aggression," "Learning: Psychoanalytic and Gestalt Interpretations" and "Rorschach's Test: Current Progress with This Instrument as an Aid in Diagnosis and Therapy".

National Conference on Medical Service—The seventeenth annual meeting of the National Conference on Medical Service will be held at the Palmer House, Chicago, February 14 under the presidency of Dr. Joseph D. McCarthy, Omaha. "Analysis of Current Trends in the Control of Medicine" will be the theme of the morning session with the following speakers:

Dr. John J. Carey, Milwaukee: Effect on Medical Education.
Dr. Roy B. Harris, New Orleans: Significance to Medical Licensure.
J. B. Robinson, D.D.S., Baltimore: Outlook for Dentistry.
Dr. Claude W. Munger, New York: Hospital Problems.
Dr. Alfred W. Adson, Rochester, Minn.: The Doctor of Medicine and His Responsibilities.

The noonday dinner will be addressed by the Hon. Harold H. Burton, LL.D., Washington, D. C., United States Senator from Ohio on "America Looks Ahead". Dr. McCarthy will also deliver his presidential address at this session. In the afternoon the following will speak on "Medicine in the Postwar Era":

Dr. Rollo K. Packard, Chicago: Return of the Medical Officer to Private Practice.
Dr. Carl H. McCaskey, Indianapolis: Responsibility to the War Veteran.
Dr. Carl F. Volz, St. Louis: Extension of the Social Security Program.
Dr. Ransom D. Bernard, Clinton, Iowa: Expansion of Public Health.

Obstetrics Prize—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons announces that all manuscripts in its foundation prize award contest must be received by the secretary before June 1. The award shall consist of \$150 and eligible contestants include interns, residents, graduate students in obstetrics, gynecology, abdominal surgery and physicians with an M.D. degree who are actively practicing or teaching obstetrics, gynecology and abdominal surgery. Manuscripts must be presented under a nom de plume together with a sealed envelop bearing the nom de plume and containing a card showing the name and address of the contestant. Manuscripts must be limited to five thousand words and must be typewritten in double space on one side of the sheet. Illustrations should be limited to such as are required for a clear exposition of the thesis. The successful thesis shall become the property of the association but this provision shall in no way interfere with the publication of the communication in the journal of the author's choice. Free copies of all manuscripts and illustrations must be submitted. The award

will be made at the annual meeting of the association at which time the successful contestant must appear in person to present his paper as a part of the regular scientific program. The contestant must meet all expenses incident to the presentation. Dr. James R. Bloss, 418 Eleventh Street, Huntington, W. Va., is the secretary of the association.

Tropical Medicine Study Begins at Tulane—On January 4 twenty-nine persons began classes in the study of tropical medicine at Tulane University of Louisiana School of Medicine, New Orleans. After completing their training, all will return to their own medical schools to teach. The group includes:

Dr. Gilbert D. Curtis, College of Medical Evangelists, Los Angeles, Loma Linda.
Dr. Morris Tager, Yale University, New Haven, Conn.
Dr. William Platt Emory University, Atlanta, Ga.
Dr. Carroll L. Birch, University of Illinois, Chicago.
James A. Kennedy, Ph.D., University of Louisville, Ky.
Dr. Walter A. Stryker, University of Michigan, Ann Arbor.
Dr. William J. Pyles, Columbia University College of Physicians and Surgeons, New York.
Dr. Roger D. Baker, Duke University, Durham, N. C.
Dr. Arnold G. Wedum, University of Cincinnati.
Dr. Matthew C. Riddle, University of Oregon, Portland.
Dr. Hunter S. Cook, Hahnemann Medical College and Hospital of Philadelphia.
Dr. Eleanor H. Valentine, Woman's Medical College of Pennsylvania, Philadelphia.
Dr. Francis D. Smith, University of Virginia, Charlottesville.
Dr. Gerald R. Collier, University of Western Ontario, London, Canada.
Dr. James Z. Davis, University of Utah, Salt Lake City.
Leslie G. Saunders, Ph.D., University of Saskatchewan, Saskatoon, Canada.
Dr. Lloyd J. Florio, University of Colorado, Denver.
Lois C. Lillich, Ph.D., New York Medical College.
Justus F. Mueller, Ph.D., Syracuse University, Syracuse, N. Y.
Thomas J. Brooks, Jr., Ph.D., Wake Forest College, Winston-Salem, N. C.
Angus M. Griffin, Ph.D., George Washington University, Washington, D. C.
Dr. Albert H. Meier, Northwestern University, Chicago.
Dr. Jacob Furth, Cornell University, New York.
Dr. Robert M. Shaw, University of Alberta, Edmonton, Canada.
Anna D. Dulaney, Ph.D., University of Tennessee, Memphis.
Dr. William Kaufmann, Albany Medical College, Albany, N. Y.
Dr. Richard C. Porter, University of Buffalo.
James Fred Denton, Jr., Ph.D., University of Georgia, Augusta.
Millard F. Gunderson, Ph.D., University of Nebraska, Omaha.

The project was described in *THE JOURNAL*, Dec. 19, 1942, page 1329. It was made possible by a grant of \$25,000 through the Association of American Medical Colleges by the John and Mary R. Markle Foundation.

Report of Industrial Hygiene Foundation—With war industries losing manpower at the rate of one hundred and thirty-six million workdays per year, or an average of more than two and one half million workdays weekly, through illness alone, special studies are now going forward to help reduce sick absenteeism in the industries by the Industrial Hygiene Foundation, Pittsburgh, and a group of its member companies in collaboration with the U. S. Public Health Service according to the annual report of the managing director of the foundation. Statistics are now complete for fourteen of the participating companies for the year 1941 covering absences of eight days or over. In 1942 eleven more companies and associations affiliated with the foundation in an effort to promote healthful working conditions, bringing the total to 246 company and association members in the foundation. These organizations, practically all of them engaged in war production employ between two and three million war workers. More plant hygiene surveys were conducted in 1942 than in any previous year. The introduction of unfamiliar and new chemicals in manufacturing processes, some with little known toxic effect is demanding even greater attention to hygiene measures. Meanwhile, it was stated the dermatoses continue to be the most common of all occupational diseases. Continued support was noted for medical and engineering research in industrial health with grants to the Saranac Laboratory, N. Y., the University of Pennsylvania, Philadelphia and Harvard School of Public Health, Boston. A study in toxicology is under way for a member company at Mellon Institute, Pittsburgh. Two medical and two engineering bulletins were issued to members during the year. Comparison of Stereoscopic Miniature Chest Films, Single Roentgenograms on Paper and Single Roentgenograms on Large Films, Effects of Exposure to Welding Fumes and Gases Upon Normal and Tuberculous Animals, Air Flow Measurement by the Dilution Method and Measuring Air Flow in Industrial Ventilation. More than one thousand abstracts of articles, legal decisions and news items relating to industrial health have been carried in the foundation's *Monthly Hygiene Digest* during the past year. As a wartime measure the foundation's board of trustees has authorized the extension of service to nonmember companies on a cost plus basis which includes plant hygiene surveys now being conducted in all types of manufacturing.

Annual Report of Foundation for Infantile Paralysis—The National Foundation for Infantile Paralysis disbursed \$1,142,009.35 in seventy-seven grants and appropriations during the fiscal year ended Sept. 30, 1942. The money went to medical schools, hospitals, research laboratories, health institutes and foundations from funds raised by the March of Dimes and celebrations of President Roosevelt's birthday. During the year 450 county chapters of the foundation were formed so that now 2,900 of America's 3,070 counties are serviced by about 40,000 volunteer workers. The foundation reports that its achievements during the year were the teaching of the Kenny method of treating after-effects which entailed establishment of special training programs to provide physicians, nurses and physical therapists to apply and carry on the method, broadening of study in search of a prevention and real cure, addition not only to knowledge of the nature of the virus but also the method of spread of the infection and emphasis of the little appreciated role of spasm and other temporary symptoms which if untreated result in permanent damage and correlation of the study of infantile paralysis with studies of related encephalitis infections. For virus research the foundation made twenty-three grants to twenty-one institutions for a total of \$543,749.46. Of the grants, seven were to men or institutions whose work had not been previously supported by the foundation. Among the grants were \$59,244 to Johns Hopkins University School of Hygiene and Public Health, Baltimore (the term of this grant is five years and the total approved for that period is \$500,000), \$40,000 to the University of Michigan School of Public Health, Ann Arbor, \$21,526 to George Williams Hooper Foundation of the University of California, San Francisco, two grants totaling \$21,510 to the Michigan Department of Health, Lansing, \$16,000 to Yale University School of Medicine, New Haven, Conn., two grants totaling \$13,255.25 to the University of Minnesota Medical School, Minneapolis, \$12,400 to the Children's Hospital Research Foundation of the University of Cincinnati College of Medicine, \$10,860 to the University of Toronto Connaught Laboratories, Canada, \$10,000 to Stanford University School of Medicine, San Francisco, and \$10,000 to the University of Southern California School of Medicine, Los Angeles. To carry on after effects work the foundation made twenty-three grants to sixteen institutions in twelve states and Canada, among them being ten new grants. The total including one appropriation was \$88,286.35. Among the grants were three grants totaling \$11,893.38 to the State University of Iowa College of Medicine, Iowa City, \$9,200 to the University of Rochester School of Medicine and Dentistry, New York, two grants totaling \$7,975 to the Massachusetts General Hospital, Boston, \$7,050 to the University of Minnesota Medical School, two grants totaling \$7,000 to the University of Colorado School of Medicine, Denver, and \$5,900 to the Columbia University College of Physicians and Surgeons, New York. For educational purposes there were three appropriations and twelve grants to ten institutions in seven states, the total amount being \$227,540.80. Principal grants were \$6,000 to Teachers College of Columbia University, New York, three grants totaling \$34,280 to the National Organization for Public Health Nursing, Inc., New York, \$50,120 to the Georgia Warm Springs Foundation, \$16,695 to the University of Minnesota Medical School, \$10,400 to Northwestern University Medical School, Chicago, \$10,000 to the Harvard Infantile Paralysis Commission, Boston, \$9,520 to Stanford University School of Health (Women), Palo Alto, Calif., \$5,000 to the American Physiotherapy Association, Palo Alto, and \$4,500 to the D. T. Watson School of Physiotherapy, Leetsdale, Pa. For epidemics and public health work there were five grants and eight appropriations totaling \$27,432.76. The grants were \$8,950 to the Illinois Committee on Infantile Paralysis in joint cooperation with the Cook County Public Health Unit and Illinois Department of Public Health, Chicago, \$3,600 to the New York State Department of Health, Albany, \$1,080 to the Children's Hospital, Winnipeg, Canada, \$940.72 to Vanderbilt University School of Medicine, Nashville, Tenn., and \$500 to the Louisiana State University School of Medicine, New Orleans. Among the miscellaneous appropriations was \$30,000 for operation of the infantile paralysis center at Tuskegee Institute, Alabama, which provides after care for Negro orthopedic cases, also \$225,000 to the Georgia Warm Springs Foundation to conduct its work and research studies. To make the Kenny method of treatment available to patients in all parts of the country the National Foundation enlarged its training course at the University of Minnesota, added six courses at different centers throughout the country and set up scholarships for training physicians, nurses and physical therapists in this method.

Foreign Letters

BUENOS AIRES

(From Our Regular Correspondent)

Dec 18, 1942

Epidemic of Acute Anterior Poliomyelitis

The number of cases of acute anterior poliomyelitis in Argentina since last November has been larger than those of previous epidemics. The acute course of the disease is similar to that of the 1936 epidemics. About 400 cases have been reported in two months in the epidemic area, in which more than 700 cases were observed during the whole epidemic period of five months in 1936. A permanent committee for the crusade against the disease has been recently organized. Separate wards and 600 beds in various hospitals have been reserved for patients with the disease. The proper measures for controlling the epidemics as well as negotiations which aim at the creation of a scientific institute for researches on the disease as it develops in Argentina are in course. Dr Enrique Chaveaux, the director of the Instituto de las Enfermedades Infecciosas y de Higiene of Montevideo Uruguay recently reported good results from the administration of tetanus toxin to patients with the disease. The treatment is said to be reliable and harmless provided the toxin is administered in the proper dose.

New Hospital Center

Dr Juan M. Obarrio, a psychiatrist, recently presented a plan for the creation of a hospital for the diagnosis and treatment of psychoneuro endocrine diseases which will be called the Hospital Intermedio. The hospital will function as a center for the diagnosis and therapy of diseases of the nervous system and of the endocrine glands. The patients will be treated as ambulatory before hospitalization whenever this treatment is indicated. All the necessary services and facilities for the treatment of special diseases will be included. There will be a department for social work. Dr Gonzalo Boschi, a psychiatrist and the director of an important hospital for the insane in Buenos Aires, said that the number of beds in municipal asylums is insufficient and that the creation of a hospital in accordance with Dr Obarrio's plans is of paramount importance.

The municipal council voted unanimously for the creation of the Hospital Intermedio. The money for the construction, equipment and maintenance of the hospital is already provided for. There is a municipal fund in Buenos Aires, which is collected during the year in the form of a 5 per cent tax on theater tickets. Up to now the fund has been used for the building and maintenance of hospitals for the insane and homes for old people. This fund is now available for the Hospital Intermedio. The total amount of the tax in 1942 was about 1,200,000 Argentine pesos (\$300,000).

Epidemic Encephalomyelitis

Dr Rene Crouchet of the Faculty of Medicine of Bordeaux recently gave a lecture in the Hospital de Clínicos in Buenos Aires. He discussed epidemic encephalomyelitis (Crouchet's disease). He concluded that epidemic encephalomyelitis is a polymorphous disease with a variety of clinical forms. In the typical clinical form of the disease the symptoms are somnolence, moderate fever and visual disorders (diplopia). The diagnosis is difficult, as the symptoms are those of common grip. It is easier in epidemic seasons during which the prognosis is grave with an approximate mortality of 10 per cent. Sequels especially postencephalitic parkinsonism, appear late after apparent cures. The lesions of the nervous tissues from localization of a filtrable virus are similar to those caused by rabies or poliomyelitis virus. The disease was recognized as such for the first time in 1915 and 1916 in the war zones of the French army (regions of Commercy and Verdun). From

these regions the disease extended to France, the colonies and several foreign countries. The intravenous injections of dextrose and sodium salicylate is the therapy of choice in acute forms of the disease.

Medical and Surgical Meetings

The fourteenth Argentine Congress of Surgery, which was organized by the Argentine Association of Surgery, was recently held in Buenos Aires. Dr Carlos Roberto Lavallo is the president. The speakers were Drs Rafael J. Babbina, Oscar Vaccarezza, Wenceslao Tejerina, Rotheringham and Alejandro Pavlovsky who discussed "Nontraumatic Medullary Compression," "Thoracic Trauma" and "Etiology, Pathogenesis, Diagnosis and Therapy of Acute Pancreatitis" respectively. The topics to be discussed in the next Argentine Congress of Surgery are "Preoperative and Postoperative Periods in Surgery of the Liver and Bile Ducts," "Treatment of Genital Prolapse and Its Results" and "Trauma of Carpal Bones."—The first Inter American Congress of Surgery was held at Santiago, Chile, on November 14, on the occasion of the centennial anniversary of the foundation of the University of Chile. Delegations from the United States and Canada and other Pan American countries were present.—The second Latin American Congress of Plastic Surgery was recently held in Buenos Aires. Dr Lelio Zeno, surgeon, of Buenos Aires, is the president. There were several important official topics discussed, including Labioplasty Fissure." The next Latin American Congress of Plastic Surgery will be held in Chile. The official topics will include "Plastic Surgery of the Hand" and "Treatment of Scars."—The third Pan American Congress of Endocrinology, which was to meet in Buenos Aires in the course of 1943, has been postponed on account of the war. The exact date will be decided later on.—The Pan American Neuropsychiatric Week, which was to take place in Buenos Aires early in the course of 1943, has been postponed till November 1943.—The first National Conference of Normal and Pathologic Anatomy, Histology and Embryology was recently held in Cordoba. Dr Humberto Freccassi was the president. Brazil, Chile, the United States, Paraguay and Uruguay accepted the invitations extended to them and sent delegations.—The first Argentine Congress on Endemic and Epidemic Diseases was held in Buenos Aires in November 1942. Dr Carlos Gonso Gandolfo, professor of epidemiology in the Faculty of Medicine of Buenos Aires, is the president. The official topics were diphtheria, exanthematic typhus, infectious in Latin America not previously recognized, acute anterior poliomyelitis (Henne Medin disease), brucellosis, diseases of the respiratory tract caused by viruses and miscellaneous topics on endemic diseases and infections. The next congress will be a Pan American Congress on Endemic and Epidemic Diseases. It will be held in Montevideo in November.

Sanitary Conference

The government of Argentina recently appointed a committee to organize a sanitary conference. Dr Juan Jacobo Sprungenberg, the president of the Departamento Nacional de Higiene, was appointed president of the organizing committee. The sanitary conference will be held in Buenos Aires at a later date. The aim of the conference is to organize national centers of social care and public health in such a manner as to have a coordinated system throughout the country.

New Scholarships

The Academia Nacional de Medicina of Buenos Aires recently established the Hirsch Medical Scholarships with a fund of 500,000 pesos (about \$125,000), which was donated by Mr Alfredo Hirsch of Buenos Aires. The medical studies with these scholarships will be made in the United States or in England for two years beginning by the middle of 1943. For the first ten years the scholarships will be given for studies on cancer, leprosy and infantile paralysis.

Deaths

Elmer Burkitt Freeman • Baltimore, Baltimore Medical College, 1900 specialist certified by the American Board of Internal Medicine, member of the American Gastroenterological Association and the National Gastroenterological Association, fellow of the American College of Physicians member of the Southern Medical Association and secretary of its section on gastroenterology in 1930 and 1931 and chairman in 1932, fellow of the Premier Congres international de gastroenterologie, formerly clinical professor of gastroenterology at the University of Maryland School of Medicine and College of Physicians and Surgeons associate in clinical medicine at the Johns Hopkins University School of Medicine since 1929, formerly lecturer on medicine at his alma mater gastroenterologist St Agnes' Hospital since 1910 dispensary physician gastrointestinal department, Johns Hopkins Hospital, since 1912 and assistant visiting physician at the hospital since 1929 visiting physician at the Bon Secours Hospital from 1917 to 1938 and attending gastroenterologist since 1938 visiting physician to the Church Home and Infirmary since 1929 member of the associate staff, Union Memorial Hospital, from 1936 to 1938 and since 1938 a member of the active staff, since 1917 physician in chief, Maryland General Hospital, where he died December 23, of myocardial infarction with cerebral embolus, aged 67

John Rathbone Oliver, Baltimore Leopold Franzens-Universität Medizinische Fakultät Innsbruck, Austria 1912 served as priest at the Protestant Episcopal Church in 1900 and as curate at St Mark's Church Philadelphia 1900-1903, when he resigned was restored to the orders in 1927 member of the Medical and Chirurgial Faculty of Maryland the American Psychiatric Association the Royal Society of Medicine the Phi Beta Kappa and the Association for Research in Nervous and Mental Disease professor of the history of medicine at the University of Maryland School of Medicine and College of Physicians and Surgeons from 1927 to 1930 and associate in the history of medicine at Johns Hopkins University School of Medicine from 1930 to 1939 surgeon in the Austrian Army, 1914-1915, psychiatrist, Johns Hopkins Hospital, from 1915 to 1917, chief medical officer to the Supreme Bench of Baltimore from 1917 to 1930 member of the Medical Officers' Reserve Corps received the degree of doctor of philosophy from Johns Hopkins University in 1927, author of many books including "The Good Shepherd," "Fear," "Psychiatry and Mental Health" "Tomorrow's Faith," "Priest or Pagan" and "Spontaneous Combustion", aged 71, died, January 21, in the McLean Hospital, Belmont of bronchopneumonia

Leslie Lawson Bigelow • Columbus, Ohio Harvard Medical School, Boston 1906 acting dean and clinical professor of surgery at the Ohio State University College of Medicine, where he had been a member of the faculty since 1914, past president of the Ohio State Medical Association and the Columbus Academy of Medicine, fellow of the American College of Surgeons acting director of the Starling-Loving University Hospital surgeon and chief of staff of the Children's Hospital, surgeon to the Grant and St Francis hospitals at one time served as a delegate to the British Medical Association and the Institute of Public Health in Zurich Switzerland, formerly chief surgeon for the old Hocking Valley Railroad, president of the Harvard Medical Alumni Association 1940-1941 aged 62, died January 15 of embolism following an operation

Louis Joseph Seibert, Toronto Ont Canada, University of Toronto Faculty of Medicine 1912 specialist certified by the American Board of Ophthalmology member of the American Academy of Ophthalmology and Otolaryngology head of the department of ophthalmology at St Michael's Hospital for many years on the staff of the Hospital for Sick Children consultant at St Joseph's Hospital since it was founded in 1921 served as a captain in the medical corps of the Canadian Army during World War I for many years a member of the athletic board of the University of Toronto in 1928 was elected to the board of education of Toronto representing the separate schools in 1908 represented Canada at the Olympic games at London, England aged 56 died December 2

Henry H Foringer, Elizabethtown Pa, Western Reserve University Medical Department, Cleveland, 1883 member of the Medical Society of the State of Pennsylvania, at one time a member of the staff of St Vincent's Hospital and resident physician at the Pennsylvania Soldiers and Sailors Home Erie in 1936 in honor of his fifty years in the prac-

tice of medicine a testimonial dinner was given him by the Erie County Medical Society, aged 88 died December 9 in the Philadelphia Freemasons Memorial Hospital, Masonic Homes of carcinoma of the stomach and prostate

Francis Joseph Carr, Buffalo, Niagara University Medical Department, Buffalo 1894 member of the Medical Society of the State of New York fellow of the American College of Surgeons attending surgeon Emergency Hospital consulting surgeon Mercy and Millard Fillmore hospitals and Buffalo Hospital of the Sisters of Charity Buffalo St Mary's Hospital, Niagara Falls J N Adam Memorial Hospital Pervsburg St Francis Asylum, Buffalo and Gardenville and Our Lady of the Angels Home, Williamsville, aged 79 died December 10 of cerebral hemorrhage

William David Barry • Smethport Pa, Jefferson Medical College of Philadelphia 1909 served as a first lieutenant in the medical corps of the U S Army during World War I served as a member of the county war price and rationing board number 1 and as chairman of the board at Smethport formerly a member of the staff of the Wills Eye Hospital Philadelphia aged 60 died December 5 in Bradford of coronary thrombosis

Archibald Bee, Florence Colo Starling Medical College, Columbus 1890 member of the Colorado State Medical Society served during World War I aged 77 died December 5 in the Camden Clark Memorial Hospital Parkersburg W Va of carcinoma of the lung

Samuel Dey Bennett, Millville N J Jefferson Medical College of Philadelphia 1896, member of the Medical Society of New Jersey, served several years as school physician for the board of education of Millville, aged 70 died December 3 of carcinoma of the throat

J W Edward Bitter • Quincy Ill, Quincy College of Medicine, 1887 served as president of the Adams County Medical Society in 1929 and in 1933 and as secretary 1922-1923 in 1936 was honored by the society on the occasion of his fiftieth anniversary in the practice of medicine on the staff of St Mary Hospital aged 80, died December 17 of cerebral hemorrhage

Volney T Boaz, Manson Wash Baltimore Medical College 1895 also a pharmacist veteran of the Spanish-American War, surgeon for the Santa Fe and Frisco Railroad served as a member of the board of education and as county coroner, aged 81, died, November 19, of cerebral hemorrhage

John Erskine Burns, New Dennison Ill St Louis College of Physicians and Surgeons 1902 member of the Illinois State Medical Society aged 65 died December 2, in the Herrin (Ill) Hospital of heart disease

Alan Duncan Calhoun • Richmond Heights Mo Washington University School of Medicine St Louis 1935 instructor in clinical ophthalmology at his alma mater assistant ophthalmologist Barnes and St Louis Children's hospitals assistant ophthalmologist to outpatients University Clinics specialist certified by the American Board of Ophthalmology aged 35 died, December 15 of subarachnoid hemorrhage and rupture of a cerebral aneurysm

Samuel Handly Caraway, Indianapolis Medical College of Ohio Cincinnati 1893 served as a captain in the medical corps of the U S Army during World War I aged 76 died, December 14, in the Veterans Administration Facility, Marion, of lobar pneumonia

Booton Stover Compton, Atlanta, Ga University of Maryland School of Medicine Baltimore 1910 on the staff of the Veterans Administration Facility aged 59 died, December 26 of a fracture received in a fall in his home

Daniel Newman Cone, White Springs Fla University of Virginia Department of Medicine, Charlottesville, 1899 member of the Florida Medical Association, formerly served as state senator and as director of the bureau of epidemiology state board of health, at one time surgeon in the U S Public Health Service Reserve, aged 67, died, December 1, of lympho sarcomatosis

J Arthur Cormier, Rochester, N Y Laval University Medical Faculty, Montreal Que Canada 1883, for many years physician at St Joseph's Orphanage aged 82 on the staff of St Mary's Hospital, where he died, December 11, of coronary thrombosis

Linn M Cudworth, Perry Mich Baltimore University School of Medicine, 1896 in 1940 was selected from a group of nominees in a popular radio program as the typical American small town doctor aged 72, died, December 9, of pernicious anemia

William Leslie Davenport, Amelia C. H., Va. College of Physicians and Surgeons, Baltimore, 1893, member of the Medical Society of Virginia, aged 81, died, December 22, of coronary thrombosis.

Robert Brewer Dixon * Boston Harvard Medical School, Boston, 1879, aged 86, died, December 16, of bronchopneumonia.

James M. Goldman, Vincennes Ind., Eclectic Medical Institute, Cincinnati 1896, served as county physician for many years and as deputy county coroner, aged 74, died December 20, in the Good Samaritan Hospital of angina pectoris.

Channing Hall * Oakland Calif., Cooper Medical College San Francisco 1911, fellow of the American College of Surgeons, served overseas as a captain in the medical corps of the U. S. Army during World War I, recently chairman of the Selective Service Board number 63, aged 57, on the staffs of the Samuel Merritt Hospital, the Peralta Hospital and the Alameda (Calif.) Hospital, where he died, December 14, of pneumonia.

Alva Curtis Hamblin, Valrico, Fla., Chattanooga (Tenn.) Medical College, 1892, past president of the Hillsborough County Medical Society, port physician during the Spanish-American War, formerly county physician for Hillsborough County for many years, district health officer for the state board of health, at one time health officer for Tampa, aged 83, died, December 6, of chronic prostatic hypertrophy and uremia.

Charles A. Handley, Brocton, Ill., Louisville (Ky.) Medical College, 1894, aged 74, died, December 13, of cerebral hemorrhage.

Grove Harkness, Minocqua Wis., Rush Medical College, Chicago, 1890, aged 82, died, December 12, in a hospital at Milwaukee of heart disease.

Allan Harris, Greenwich N. J., Baltimore Medical College 1902, member of the Medical Society of New Jersey, aged 69, died November 2, of coronary embolus, arteriosclerosis and hemiplegia.

Hazel May Hatfield, Woodcliff Lake N. J., Cornell University Medical College, New York 1907, for many years associated with the department of health of New York City, aged 59, died, December 4, in the Hackensack (N. J.) Hospital.

Robert Hessler, Indianapolis, Medical College of Indiana Indianapolis, 1891, aged 81, died, December 17, of cerebral sclerosis.

Amon S. Hill, Panama City, Fla., Atlanta (Ga.) Medical College 1891, served on the staff of the Panama City Hospital, for many years president of the First National Bank, aged 81, died December 9, of nephritis.

George Arthur Holliday, Traverse City, Mich., Detroit College of Medicine, 1904, member of the Michigan State Medical Society, formerly a dentist, served in the U. S. Navy during World War I and later was transferred to the medical corps of the U. S. Army with rank of major, served as a transport surgeon until eighteen months after the Armistice, major in the medical reserve corps, U. S. Army, not on active duty, for many years health officer of Traverse City, aged 75, died October 30, of cerebral hemorrhage.

Isaac H. Hornsby, Whiteville, Tenn., Memphis Hospital Medical College 1885, formerly chairman of the board of education, aged 93, died December 15, of coronary occlusion.

W. J. Hutto, Bee Branch, Ark. (licensed in Arkansas in 1903), aged 71, died December 12, of arteriosclerosis.

Robert S. Kirk, Baltimore, Baltimore Medical College, 1896, on the staff of the Church Home and Infirmary, aged 71, died, December 1, of pneumonia.

Henry Clay Knapp * Huntingburg Ind., Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906, aged 76, died December 4, of angina pectoris.

Isidore Harry Kugel, Brooklyn, Long Island College Hospital Brooklyn 1917, member of the Medical Society of the State of New York, aged 50, died, December 23, of heart disease.

Oliver Morton Layton, Fond du Lac, Wis., Rush Medical College Chicago, 1895, member of the State Medical Society of Wisconsin, fellow of the American College of Physicians on the staff of the St. Agnes Hospital, aged 71, died, December 27, of heart disease.

Mason B. Light * Indianapolis, Indiana University School of Medicine, Indianapolis 1910, served as a captain in the medical corps of the U. S. Army during World War I, aged 53, on the staffs of the Indianapolis City Hospital, St. Francis Hospital, Methodist Hospital and St. Vincent's Hospital, where he died December 19, of carcinoma.

Frank G. Lightner, Sabina, Ohio, Medical College of Ohio, Cincinnati 1890, aged 75, died, December 13, in Washington C. H. of arteriosclerosis.

Bert Duane Longe, Newport, Vt., University of Vermont College of Medicine, Burlington 1896, at one time secretary and treasurer of the Orleans County Medical Society, aged 73, died December 14, of diabetes mellitus and myocardial degeneration.

Charles Reese Longworth, San Diego Calif., Ohio Medical University Columbus, 1904, aged 73, died, December 2.

Bertha Goba Macbeth, Fort Wayne, Ind., Fort Wayne College of Medicine 1905, member of the Indiana State Medical Association, aged 68, died December 15, in the Methodist Hospital of aortic obstruction.

Ralph Heminway Marsh, Guilford Maine, Medical School of Maine Portland 1893, member and past president of the Maine Medical Association, past president of the Piscataquis County Medical Society, had served as county medical examiner and special pension examiner, was on the medical advisory board of his district during World War I, at the June 1942 annual session of the Maine Medical Association was presented with the association's gold medal in recognition of fifty years in the practice of medicine, aged 79, died, October 27.

Leon Matassarini * Leavenworth, Kan., Universitatea din Bucuresti Facultatea de Medicina Rumania, 1901, past president and secretary of the Leavenworth County Medical Society, served in France and as a lieutenant colonel in the medical corps of the U. S. Army during World War I, colonel in the medical reserve corps, not on active duty, for several years served as a member of the board of education of Leavenworth, on the staffs of the Cushing Memorial and St. John's hospitals, aged 64, died December 6, of coronary occlusion.

William Markle Miller, Cabery Ill., Rush Medical College Chicago 1894, had served as mayor of Cabery village, trustee, school director and a member of the board of education in 1942, was presented with a gold medal by the Illinois Central Railroad in award in recognition of fifty years of service as a railroad surgeon, aged 83, died, December 14, of heart disease.

George Lone Monson * Denver, Denver and Gross College of Medicine, 1905, formerly clinical instructor of obstetrics at his alma mater, aged 60, died December 7, of poison self administered.

James E. New, Dexter Ga., University of Georgia Medical Department, Augusta 1900, member of the Medical Association of Georgia, chairman of the Laurens County Welfare Board, past president of the Laurens County Medical Society, served several terms as mayor of Dexter, was chairman of the board of education of Dexter and a director in the Citizens and Southern Bank of Dublin, aged 65, died, December 11, in a hospital at Dublin of pneumonia.

William Drummond Radcliffe * Belen N. M., Cleveland Medical College Homeopathic 1894, for many years a member of the state board of health, health officer of District number 8 consisting of Catron Socorro Torrance and Valencia counties, aged 77, died December 12, of coronary thrombosis.

Frederick King Rogers, Lawrence Kan., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912, aged 55, died, December 3, of coronary sclerosis.

Wilfred Sefton, Auburn N. Y., Harvard Medical School Boston 1918, member of the Medical Society of the State of New York, aged 50, on the staff of the Mercy Hospital and Auburn City Hospital, where he died, November 4, of pneumonia (virus).

John William Shaffer * Youngstown, Ohio, Ohio Medical University Columbus 1898, senior surgeon for many years on the staff of St. Elizabeth's Hospital, aged 69, died, December 3, of sarcoma of the nasopharynx.

Frank Pulliam Smith, Fort Worth, Texas, University of Louisville (Ky.) Medical Department 1911, member of the State Medical Association of Texas, formerly served as health officer of Tarrant County, aged 59, died, December 1, of heart disease.

Ernest Hampton Updike, Mill Creek, W. Va., Bennett Medical College, Chicago, 1915, aged 65, died, December 4, of cerebral thrombosis.

Harry W. Watts, Pembroke Ky., Louisville (Ky.) Medical College, 1894, member of the Kentucky State Medical Association, director of the Peoples' Bank and member of the school board of Pembroke, aged 70, died, December 9, of bulbar paralysis and pneumonia.

Bureau of Investigation

DANGEROUS TO HEALTH

Because of Inadequate Warnings on Labels

[EDITORIAL NOTE—These abstracts differ from other abstracts of Notices of Judgment issued by the Food and Drug Administration of the Federal Security Agency which have appeared in these pages in that they deal with nostrums which were misbranded because their labels failed to carry adequate warnings against giving them to children or using them in those pathologic conditions in which they might be dangerous to health, or caution against unsafe dosages or methods or duration of administration or application, for the protection of the user. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Aesculus Pile Cerate—C F Breitenbach (Mucine Company) Chicago Composition essentially ichthammol tar oil and extractives of plant drugs and petrolatum. Misbranded because designation Pile Cerate and statement relieves bleeding itching blind protruding ulcerated piles on carton were false and misleading. Further misbranded because label failed to bear name and place of business of manufacturer packer or distributor since reference to 'Ainsworth Specialty Co Kansas City Mo' did not make clear this concern's connection with the product and because label did not give the common or usual name of each active ingredient or its quantity. Also misbranded because labeling failed to warn against use of the product by children or in those pathologic conditions in which its employment might be dangerous to health or caution against unsafe dosage or methods or duration of administration for protection of user.—[D D N J F D C 436 September 1942]

Argosine—C F Breitenbach (Mucine Company) Chicago Composition a silver substance such as argyrol an extract of a plant drug and water. Misbranded because label failed to bear the common or usual names of the active ingredients as well as name and place of business of manufacturer packer or distributor since the name and address Ainsworth Specialty Company Kansas City Mo appearing on the carton were not those of the manufacturer and did not reveal any connection of this firm with the product. Further misbranded because unlabeled portion of Argosine failed to bear required statement as to quantity of contents and because of false and misleading statements made regarding the therapeutic properties of the product which alleged properties were not named in the government's abstract of the case. Also misbranded because label did not contain adequate directions for taking or sufficient warnings against use by children or in those pathologic conditions in which it might be dangerous to health or caution against unsafe dosages or methods or duration of administration or application for protection of user.—[D D N J F D C 436 September 1942]

Cascarin Compound Tablets—Boyce Pharmacal Company Los Angeles Shipped July 10 1940 Composition in each tablet alkaloidal material including about 0.024 grain of strychnine sulfate $\frac{1}{8}$ grain of podophyllin and $\frac{1}{8}$ grain of aloin and an emodinbearing drug such as cascara sagrada. Misbranded because label failed to warn adequately against use by children or in those pathologic conditions in which it might be dangerous to health or caution against unsafe dosage or duration of administration, since label did not warn purchaser that the product should not be taken when symptoms of appendicitis are present and that its use by children and elderly persons was particularly dangerous or caution against frequent or continued use which might cause dependence on laxatives to move the bowels. Further misbranded because name Cascarin Compound falsely suggested that the essential ingredient of the product was derived from a species of cascara whereas its principal active ingredients were aloin podophyllin and strychnine because designation Dr Hinkle No 3 gave the false impression that the mixture had the essential composition designated for Hinkle's pills in the National Formulary whereas the composition differed therefrom and because the label failed to list the common or usual name of each of the active ingredients since the word Cascarin was coined and hence was not the common or usual name of any drug.—[D D N J F D C 440 September 1942]

Coldlax—Smith Brothers Drug Company Greensboro N C Shipped Dec. 10 1940 Composition essentially water alcohol sodium salicylate and an unnamed laxative plant drug with menthol camphor and traces of alkaloids. Misbranded because the product name and the statement on carton and bottle label for the relief of colds and the designation for colds in the directions were false and misleading since the product was not an adequate treatment for colds also misbranded because the unmixed statement for coughs in the directions was false and misleading since the article was not an adequate treatment for coughs from all causes further misbranded because claim Coldlax contains

no habit forming drugs was false and misleading since the product did contain aromatic fluid extract of cascara sagrada the frequent or continued use of which might cause dependence on laxative. The branded again in that the article failed to bear the common or usual name of each active ingredient since alkaloids is not the common or usual name of any constituent of this preparation and the name of other ingredients were given in abbreviated form. Further misbranded because labeling directions for its use were inadequate since they did not limit the period of time over which it might properly be taken. Finally misbranded because label did not adequately warn against use in those conditions wherein it might be dangerous to health or caution the user that it should not be taken when symptoms of appendicitis such as nausea vomiting or abdominal pain were present or that frequent or continued use might result in dependence on laxatives.—[D D N J F D C 440 September 1942]

Crawford's Sa Lax—Crawford Food Inc Los Angeles Shipped July 26 1940 Composition tablets containing the laxative drugs rhubarb root and senna leaf with Irish moss okra and leafy plant material such as parsley. Misbranded because package failed to bear adequate directions for use and stated that the dose must be determined by the severity of the case merely suggesting a general dosage which did not constitute suitable directions for the use of a laxative preparation. Misbranded also because label failed to caution adequately against use in certain pathologic conditions or methods or duration of administration for protection of users in that it did not inform the purchaser that the product would be dangerous to a person suffering from appendicitis or that its frequent or continued use might result in dependence on laxatives. Further misbranded because label falsely represented the active ingredients to be parsley and asparagus intended to maintain a higher alkalinity through the intestine and into the colon than do other vegetables of higher initial alkaline content.—[D D N J F D C 441 September 1942]

Gleet Specific—C F Breitenbach (Mucine Company) Chicago Shipped between Jan 22 and Nov 11 1940 Composition a mercury compound calculated as mercury oxymercure (0.2 per cent or 1500) eucalyptus oil and a plant drug extract all incorporated in wool wax (lanum). Misbranded because name Gleet Specific was false and misleading and because label failed to declare proportion derivative or preparation of mercury present since the label statement Mercury Oxymercure 1500 was not accurate. Further misbranded because label failed to bear name and place of business of manufacturer packer or distributor since designation Ainsworth Specialty Co Kansas City Mo did not make clear this concern's connection with the product nor did label correctly declare quantity of contents or the common or usual names of the active ingredients neither did label bear adequate directions for taking or sufficient warnings against use by children or in those pathologic conditions in which it might be dangerous to health or caution against unsafe dosages or methods or duration of administration or application for protection of user.—[D D N J F D C 446 September 1942]

Graham's Pills—Kells Company Newburgh N Y Shipped between Nov 29 1940 and Jan 25 1941 Composition essentially laxative plant drugs. Misbranded because label directions for use were inadequate in that they provided for [recommended?—Ed.] excessive dosage and label bore false and misleading claims as to product's efficacy in treating biliousness for which according to the government the pills would not be efficacious. Further misbranded because label did not carry an accurate statement of the quantity of the contents or sufficient caution against use in those pathologic conditions wherein the product might be dangerous to health or warn against unsafe dosage for the protection of users.—[D D N J F D C 445 September 1942]

Grover Graham Remedy—Kells Company Newburgh N Y Shipped between Nov 29 1940 and Jan 25 1941 Composition essentially magnesium sodium bicarbonate sodium bromide alcohol water and small amounts of chloroform ginger and peppermint oil. Misbranded because label did not give adequate directions for use chiefly in that no limitation was put on the amount of bromide that might be administered daily also misbranded because of false and misleading label claims such as that the product offered instant relief for severe attacks of indigestion and all stomach ills and was a remedy for dyspepsia gastritis and bloating further misbranded because label did not give adequate warning against use in those pathologic conditions wherein it might be dangerous to health or caution against unsafe dosage or methods of administration.—[D D N J F D C 445 September 1942]

Prostatic Deplient—C F Breitenbach (Mucine Company) Chicago Composition about 12 per cent of glycerin and 6 per cent of epsom salt with water emulsified. Misbranded because of false and misleading label claims. Highly deplient and cleansing with immediate relief of congestion of the rectal area. Used as a primary treatment on prostatic disorders (nonoperative). Further misbranded because label failed to bear name and place of business of manufacturer packer or distributor since designation Ainsworth Specialty Co Kansas City Mo did not make clear this concern's connection with the product nor did label clearly declare the quantity of contents or give the common or usual name of each active ingredient neither did label contain adequate directions for taking or sufficient warnings against use by children or in those pathologic conditions in which it might be dangerous to health or caution against unsafe dosages or methods or duration of administration or application for protection of user.—[D D N J F D C 446 September 1942]

Sterile Uteroids—C F Breitenbach (Mucine Company) Chicago Shipped between Jan 22 and Nov 11 1940 Composition essentially ichthammol menthol an iodine compound and extracts of plant drugs the whole mixture incorporated in wool wax (lanum). Misbranded because

label failed to bear name and place of business of manufacturer packer or distributor since reference to 'Ainsworth Specialty Co Kansas City Mo' did not make clear this concern's connection with the product nor did label correctly declare quantity of contents neither did label bear adequate directions for taking or sufficient warnings against use by children or in those pathologic conditions in which it might be dangerous to health or caution against unsafe dosages or methods or duration of administration or application for protection of user Further misbranded because of false statement on label that the mixture contained 10 per cent of powdered alum and 1 per cent of zinc sulfate whereas these substances were not present and because label falsely implied that this product was effective for intrauterine treatment and endometritis Adult terated because its strength differed from and its quality fell below that which it purported to possess —[D D N J F D C 436 September 1942]

SURGICAL TREATMENT OF DUODENAL ULCER

To the Editor —The generally accepted treatment of duodenal ulcer is subtotal gastric resection with the main object of reducing the secretion of hydrochloric acid, one of the causes of duodenal ulcer Many recently published articles on the subject include some such statements as are quoted from Dr Kiefer by Dr Nissen and the following "The basic prerequisites of the operation are the removal of the pylorus, a radical resection of all antral tissue and the excision of the ulcer" (Mage, Sigmund *Ann Surg* 116 729 [Nov.] 1942)

It would seem that 1 Excision of the ulcer is not always necessary If the ulcer is nonresectable," inaccessible on the posterior wall, in the distal duodenum, because of adhesions, or on account of the patient's general condition, the ulcer has many times been allowed to remain, with sometimes satisfactory results Excision of the ulcer, if convenient, is a supplement to attempts to remove or to minimize a cause is, of course, rational and advisable, though one may reasonably doubt that scar tissue remaining after excision will be more resistant to irritating acid stomach contents than was the mucosa at the site of the ulcer Removal of a cause may make removal of the ulcer unnecessary As an analogy, varicose ulcer need not always be removed, if the cause is corrected

2 Removal of the ulcer, as one author states, "to eliminate pylorospasm," seems to be rather heroic treatment Removal or minimizing of a cause, presumably hyperchlorhydria, might be successful Sacrifice of the pylorus with the substitution of an artificial, nonphysiologic, nonsplincteric, gastrojejunal communication calls for many physiologic readjustments and adaptations in the digestive processes that cause symptoms and therefore should be avoided Disturbances with or destruction of other sphincters e g pharyngeal, esophageal, cardiac, biliary, urinary or anal, disturb normal function and produce distressing symptoms Loss of control of the sphincter at the upper extremity of the intestinal tract (the pylorus) may be followed by serious disturbances despite the fact that they are not as apparent as those at the lower extremity

3 Resection of all antral tissue is a mutilating operation, based essentially on Edkins theory that the antral mucosa secretes a hormone (gastrin) that is carried to the fundus and there stimulates the secretion of hydrochloric acid This theory was presented in 1906 and has not been substantiated by experimental or clinical evidence Whether gastrin is, or is not, histamine has not been definitely settled

In 1941 I discussed Edkin's theory and its relation to peptic ulcer (*Am J Surg* 53 255 [Aug.] 1941) Objections to the sacrifice of the antrum are that the antral secretion is chiefly alkaline mucus, one of nature's buffers against excess gastric acidity and that the irritating gastric contents come in contact with the more susceptible jejunal, instead of the more tolerant duodenal, mucosa The latter fact may explain the recurrent jejunal ulcers after the Finsterer operation rather than the preservation of the antrum

Other objections to distal gastrectomy are that the antral, Brunner's and duodenal glands may have a hemopoietic function and that the antrum takes an active and important part in the physiologic, antropyloroduodenoneuromuscular mechanism that controls the opening and the closing of the gastrointestinal communication, which influences gastric tonicity, mobility, retention, evacuation, secretion and absorption Such an important structure certainly should not be sacrificed unless the necessity has been definitely proved

Granting, for argument's sake, the development of gastrin, which stimulates fundal secretion of hydrochloric acid, its obliteration by antral resection would reduce such secretion by but a fraction, as at least two other important stimuli remain intact These are psychic and hormones formed in the lower duodenum and upper jejunum are carried to the fundus by the circulation

Therefore it would seem logical from a phylogenic, embryologic, physiologic, anatomic, experimental point of view and from a small clinical experience to utilize the direct minimizing of the acid secreting fundus of the operation of subtotal gastrectomy but at the same time modifying it by preserving the important distal stomach, i e, partial fundusectomy

If this less formidable nonmutilating procedure with proper so-called medical management does not prove satisfactory, the distal stomach may then be removed for its possible indirect effect on acid secretion

GREGORY CONNELL, Oshkosh, Wis

TOTAL COLLAPSE ASSOCIATED WITH PHYSICAL EXERTION

To the Editor —I should like to comment on the two references to the paper by Colonel Suzman and myself (Mechanisms Involved in Acute Fatal Nontraumatic Collapse Associated with Exertion, *Am Heart J* 23 761 [June] 1942) made by Dr A M Master (Total Collapse Associated with Physical Exertion) in THE JOURNAL, Oct 3, 1942, page 392

We have not concluded "that severe physical exertion or trauma can produce coronary occlusion" In fact we have clearly stated that "normally no conceivable functional strain can cause fatal collapse" Regarding Master's second point, I enclose a reprint of a paper by Colonel Melzer and myself (Acute Fatal Nontraumatic Collapse During Work and Sport, *South African J M Sc* 5 4 [March] 1940) which contains the necropsy findings in 64 of the 66 cases of death associated with physical exertion on which our paper is based Of the two further observations, one has in the meantime been published in the *American Heart Journal* (Cluver, E. H., and Jokl, Ernst Sudden Death of a Rugby International After a Test Game, 24 405 [Sept.] 1942)

As the result of a regrettable oversight, the paper by Jokl and Melzer was not quoted in the list of references given by Jokl and Suzman, although complete reference to it has been made in the paper by Cluver and Jokl If Dr Master will study the pathologic material presented by Jokl and Melzer and by Cluver and Jokl he will, I trust, be satisfied that the necessary data and necropsy reports have been made available In conclusion I wish to say that our findings, far from contradicting the findings of the valuable researches by Master and his associates, on the contrary rather serve to corroborate them

As I do not know Dr Master's address, I shall appreciate it if you will let him have the enclosed reprint containing the bulk of the evidence to which you have referred in your editorial comment in the August 22 issue of THE JOURNAL, page 1431

Minnesota October Report

The Minnesota State Board of Medical Examiners report the oral written and practical examination for medical licensure held at Minneapolis Oct 20-22, 1942. The examination covered 12 subjects and included 60 questions. Fifty candidates were examined all of whom passed. Five physicians were licensed to practice medicine by reciprocity and 7 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

Missouri October Report

The Missouri State Board of Health reports the written examination for medical licensure held at Kansas City, Oct 15-17, 1942. The examination covered 15 subjects. An average of 75 per cent was required to pass. Thirteen candidates were examined, 12 of whom passed and 1 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Howard University College of Medicine	(1938)	(1942)	2
Rush Medical College	(1907)	(1942)	2
St Louis University School of Medicine	(1942)	(1942)	1

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts Amebic Dysentery Allegedly Contracted Through Negligence of Employer in Furnishing Drinking Water—In the course of his employment, Parkhurst was exposed to *Endamoeba histolytica* through the drinking water furnished on the job by the employer, a subcontractor on the project at which Parkhurst worked, and contracted amebic dysentery. He instituted proceedings for compensation under the workmen's compensation act of California, seeking an increase of 50 per cent on the applicable normal compensation allegedly because his disability was due to the serious and wilful misconduct of his employer, which additional compensation is permissible under the California act if the disability can be so attributed. The industrial accident commission found that the injury was not caused by the employer's serious and wilful misconduct and awarded normal compensation only. The workman appealed eventually to the Supreme Court of California.

Medical testimony adduced apparently before the commission disclosed that amebic dysentery is usually contracted by drinking contaminated water, that water can be contaminated by contact with fecal matter or contaminated hands and that a single person who is a carrier of the disease can infect the water supply and cause an epidemic among persons drinking the water. Apparently the water line at the project at which Parkhurst worked was attached to a pipe connecting an irrigation pump and a neighboring uncovered reservoir. When adjoining land was irrigated water from the reservoir would siphon into the water line and outlets on the job. There was evidence that the reservoir was used as a swimming pool and that tests made by county health authorities about eight months after the workman contracted the disease revealed that the water although still classified by them as good was contaminated with fecal matter. The drinking water was drawn from faucets used by the men in washing their hands on their way to and from the toilets, which were near some of the faucets. The drinking water in turn, after being drawn from the faucets, was supplied to the men on the job by an open bucket and common dipper, in violation of a California statute requiring closed containers and individual drinking cups. It further appeared that the employer commenced work as a subcontractor after the construction was under way on this particular building project and accepted the facilities furnished by the general contractor. The employer knew how the water was distributed but made no inquiry as to its source. At no time did he attempt to furnish his employees with pure, fresh drinking water. It further appeared that numerous employees had complained at various times to the superintendent on the project that the drinking water had a foul taste and odor and gave them diarrhea and cramps. While the superintendent admitted to the complaining employees that the water was bad, he excused the practice on the ground that no other water was available and that all water in that particular neighborhood had a somewhat unpleasant taste and odor. There was further evidence that a public health authority inspected the premises on the job two or three weeks prior to the onset of the dysentery in the workman and ordered the employer to desist from distributing water in open containers and common dippers.

The workman contended that in view of the foregoing evidence there was no evidence to support the commission's finding that his injury was not caused by the serious and wilful misconduct of the employer and that that misconduct is proved by the violation of the statute referred to and by the complaints by the men as to the foul condition of the water. Serious and wilful misconduct of an employer within the meaning of the workmen's compensation act, said the Supreme Court, is conduct that the employer knew, or should have known, was likely to cause serious injury, or conduct that evinces a reckless disregard for the safety of his employees. The employment of workmen under dangerous conditions that can be guarded against constitutes a reckless disregard for their safety. In this case, the

employer by knowingly violating its statutory duty to supply its employees with pure drinking water in closed containers and individual cups set the conditions for the transmission of various communicable diseases and exposed the employees to the hazard of serious injury therefrom. It is true that not every violation of a statute is serious and wilful misconduct. On the other hand, communicable diseases are readily transmitted by common drinking cups, and the statutes in the present case were designed to safeguard employees against that hazard. Violation of these statutes is particularly serious when hundreds of men are employed on the same project at the same time as here, and do not have access to other drinking water. The employer is charged with knowledge of the statute and was found by the commission to know that the water was distributed in violation of the statutory requirements. Violation of the statutes in question was not mere negligence but criminal conduct punishable as a misdemeanor.

It remains to be determined, continued the court, whether there is any evidence in the record from which the commission could find that there was no serious and wilful misconduct by the employer despite the violation of the statutes. Whether the serious and wilful misconduct of the employer caused the workman's injury is essentially a question of fact, and if there is any substantial evidence to support the findings of the commission its award will not be disturbed. On the other hand, the award of the commission will be set aside if there is no evidence to support its findings. The employer placed some emphasis on evidence in the record that the county health authorities considered the water in the reservoir safe for drinking. From that fact the employer sought to draw an inference that it could not be charged with knowledge that the water was unfit for human consumption. Actually, continued the court, the opinion of the health authorities referred only to water in the reservoir about eight months after the injury. They made no tests of the water before or at the time of the injury. While there was evidence that the president, general manager and sole stockholder of the employer corporation had on the job drunk the water from the common dipper, the most favorable inference that can be drawn from that fact is that one person did not consider the means of distribution dangerous. It has been held, however, that an employer's mistake in judgment does not relieve him from liability for serious and wilful misconduct.

Neither, in the opinion of the court, would the evidence that the drinking facilities on the job were installed by the general contractor and were used by its employees with no ill effects support the commission's finding. In fact, said the court, the commission's finding regarding the numerous complaints registered by the men destroys the pertinence of the alleged effect of the water on previous users. The testimony of the employer that it customarily accepted the facilities furnished by the general contractor and that the latter was under a contractual obligation to it with respect to such facilities indicates a misconception of its duties and liabilities with regard to the safety of its employees. The employer was aware of the general contractor's breach of contract. Its own statutory duty to furnish its employees with pure drinking water in closed containers and in individual drinking cups could not be delegated.

In the light of the findings of the commission and in the absence of substantial evidence to support its conclusion that the injury was not caused by the serious and wilful misconduct of the employer, the Supreme Court annulled the order of the commission denying additional compensation.—*Parkhurst Industrial Accident Commission* 129 P. (2d) 113 (Calif. 1942)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Ophthalmology, Cincinnati

25 1409-1530 (Dec.) 1942

Fibroblastic Overgrowth of Persistent Tunica Vascuosa Lentis in Infants Born Prematurely. III. Studies in Development and Regression of Hyaloid Artery and Tunica Vascuosa Lentis. T. L. Terry. Boston.—p. 1409.

Focal Infection. A. C. Woods. Baltimore.—p. 1423.

Eye Surgery in Wartime. E. Hartmann. New York.—p. 1448.

Great Usefulness of Birefringent Combinations in Exploration of Astigmatism. M. Marquez. Mexico. D. F. Mexico.—p. 1458.

Effect of Undercorrection and Base In Prism on Myopic Refractive State. J. Chance. E. Ogden and K. B. Stoddard. Berkeley. Calif.—p. 1471.

Evaluation of Glaucoma Operations. B. F. Payne. New York.—p. 1474.

Changes in Mineral Composition of Rat Lenses with Galactose Cataract. F. W. Salt. K. C. Swan and W. D. Paul. Iowa City.—p. 1482.

*Chemotherapy in Acute Gonococcal Conjunctivitis. L. A. Sweet. Washington. D. C.—p. 1487.

Chemotherapy in Acute Gonococcal Conjunctivitis—

Sweet emphasizes the value of the sulfonamide compounds in acute gonococcal conjunctivitis, reports the use of sulfadiazine and compares the relative efficacy of sulfanilamide, sulfapyridine, sulfathiazole and sulfadiazine in treating this condition among 102 such patients admitted to the pediatric or contagious disease wards of the Gallinger Municipal Hospital from July 1938 to April 1942. The condition of almost all the patients who responded to the sulfonamide drugs improved, the acute inflammatory reaction subsiding rapidly, the redness and edema disappearing within two or three days and the discharge stopping in four or five days. Six of the 32 patients who received sulfanilamide were resistant to the drug and 26, or 81.2 per cent, responded favorably. Only 12, or 37.5 per cent, of these patients gave negative smears within three days of treatment. Only 2 of 50 patients treated with sulfapyridine were resistant to the therapy, the 48 responding favorably. Four of the patients who received sulfapyridine had failed to respond to sulfanilamide. 1 of them was resistant to and 3 responded to sulfapyridine. Of the 50 patients 32 showed negative smears within three days of treatment. Eight patients were treated with sulfathiazole, all responded to treatment and 6 had negative smears within three days. Sixteen patients received sulfadiazine, all responded favorably and 12 had negative smears within three days. Thus, on the basis of frequency and rapidity of cure, sulfapyridine, sulfadiazine and sulfathiazole are approximately equal, and all are superior to sulfanilamide. There were no recurrences, and only one corneal ulcer occurred in the whole series. The toxic symptoms have not been striking. Slight exanthema, nausea and anemia were encountered frequently but have not been serious. Of the more severe symptoms hematuria, drug dermatitis and hyperpyrexia occurred once among the patients treated with sulfapyridine. There were no severe reactions to sulfanilamide and sulfadiazine, and only 1 patient responded unfavorably (severe conjunctival reaction) to sulfathiazole. Therefore sulfathiazole should be used in ocular infections only when other equally efficacious chemotherapeutic agents are not available for use.

American Journal of Pathology, Ann Arbor, Mich.

18 969-1184 (Nov.) 1942

Benign Chondroblastoma of Bone. Reinterpretation of So-Called Calcifying or Chondromatous Giant Cell Tumor. H. L. Jaffe and L. Lichtenstein. New York.—p. 969.

Fibrosis of Pancreas in Meat Fed Ducks. I. A. Mirsky, S. Elgart, N. Nelson and P. Wasserman. Cincinnati.—p. 1159.

Megakaryocytes in Pneumonia—By inspecting the vertebral marrow and comparing it with controls Williams demonstrated megakaryocytic hyperplasia in 26 of 306 unselected patients. For controls 16 patients dying within twelve hours of a traumatic injury were used. Primary pneumonia had occurred in 39, or 12 per cent, of the unselected patients whereas it had occurred in 17, or 65 per cent, of those with megakaryocytic hyperplasia. Counts of the megakaryocytes in the 39 with primary pneumonia revealed more than 5,000 cells per cubic millimeter of vertebral marrow in 19. There was no significant variation from the normal in the relative numbers of the types of megakaryocytes. In pneumonia there was a striking parallelism between hyperplasia of megakaryocytes and of leukoplasmic cells. This megakaryocytic and leukoblastic hyperplasia occurred in infectious diseases other than primary pneumonia and is to be regarded as a type reaction. The hyperplasia begins first in the marrow of the lumbar vertebrae and only later in the diaphysis of the humerus. The study and comparison of the marrow of the vertebrae with that of other long bones are necessary to detect and classify the reactions of the marrow.

Respiratory Function of Digestive Tract—The conclusions of Dillon on the problem of the respiratory function of the digestive tract are as follows: 1 The only place of obstruction of the lower end of the esophagus is the looplike paraesophageal muscle of the diaphragm functioning synchronously with the respiratory movements of the diaphragm. 2 The term "aerophagy" does not correspond to the mechanism of accumulation of air in the stomach and therefore it should be replaced by the more correct term "gastro-pyry". 3 The air enters the stomach and intestine of the newborn and adults during the inspiratory movements of the thorax. Swallowed air has no substantial significance. 4 In addition to pulmonary respiration, gastric respiration exists in every human being; the latter is

subsidiary but may become prevailing for example, in a person whose larynx has been extirpated because of a malignant growth. 5 The presence of air in the digestive tract of the newborn serves as proof of extrauterine respiration and that the infant was born alive. 6 The roentgen examination of a stillborn fetus in utero never reveals air in the digestive tract. 7 Correctly made roentgenograms of dead fetuses who were breathing even for a short time disclose air in the stomach or intestine. Therefore such a roentgenogram serves as a test of life. 8 A roentgenographic test of life is the most reliable and sensitive of all such available tests.

Total Body Irradiation—Irradiation of the whole body was used by Medinger and Craver for 94 patients with Hodgkin's disease, 30 with lymphosarcoma, 76 with lymphatic leukemia, 12 with myelogenous leukemia, 5 with polycythemia vera, 6 with mycosis fungoides, 11 with multiple myeloma and 35 with miscellaneous advanced carcinoma or sarcoma with generalized metastasis. The results of treating the 270 patients demonstrate that total body irradiation produces the greatest palliation in lymphomatoid disease and therefore its usefulness is largely restricted to this group of radiosensitive tumors. The greatest benefit was obtained in chronic lymphatic and myelogenous leukemia, Hodgkin's disease, lymphosarcoma and polycythemia vera. The improvement was less striking in mycosis fungoides and multiple myeloma, and there was no appreciable improvement in the 35 with generalized metastatic carcinoma or sarcoma. The survival period and the period of active useful life were prolonged in patients with Hodgkin's disease, lymphosarcoma and chronic lymphatic leukemia. Favorable palliation followed total body irradiation of patients with chronic myelogenous leukemia, polycythemia vera, mycosis fungoides and multiple myeloma. Acute lymphatic and myelogenous leukemia were not benefited. The most favorable results were obtained when local roentgen irradiation or surgery preceded total body irradiation. The aim of therapy is to obtain maximal improvement with minimal unfavorable reactions. In the determination of the dosage the guiding factors are (1) age and general resistance of the patient, (2) the disease and its extent, (3) the amount of previous irradiation, (4) the blood cell levels previous to therapy and (5) the response of the patient during treatment.

Syphilis—Siegel and his associates determined the arsenic content of the blood of patients with early syphilis receiving intensive mapharsen therapy. Characteristic and essentially similar curves were obtained for 15 patients who received mapharsen alone and 16 patients who received fever therapy with typhoid vaccine in addition to mapharsen. The daily average

of the morning low point values of arsenic in the blood of the patients who received mapharsen alone showed a progressive rise up to 16 micrograms of arsenic per hundred cubic centimeters of whole blood in the course of the first five days of treatment. The daily average of the morning low point values of the patients receiving mapharsen and fever therapy showed a prompt rise to a level of about 10 micrograms after one day of treatment, remained unchanged for three days and then rose to a level of 17 micrograms in the next three days. Comparison of results obtained by the multiple syringe method with results obtained by other observers who used the continuous drip method revealed a close parallel in the morning low point concentrations of arsenic in the blood.

Reaction to Phenytoin Sodium—Ritchie and Kolb report a fatal case of hemorrhagic erythema multiforme following the use of phenytoin sodium. Necropsy showed extensive hemorrhagic changes in the skin, mouth and gastrointestinal tract and edema of the lungs and brain. There were small pericapillary hemorrhages in the region of the third ventricle. The primary cause of death was respiratory paralysis.

- True Fatty Degeneration in Sensory Neurons of the Aged. R. C. Frueck and K. L. Zwemer. New York—p. 988.

Mesencephalic Tractotomy for Pain—Three further cases in which Walker performed mesencephalic tractotomy through an incision in the rostral portion of the pons are reported. This level seems more favorable for the section because its approach is easier and the surface markings of the pons tracts in the mesencephalon are clearer. Two reports have been published previously. Immediately after section, superficial or deep pain in the contralateral half of the body was relieved. Abdominal pain on the involved side, such as might be produced by deep palpation, was absent. The side of the body contralateral to the lesion feels "numb," "dazed" or "funny" after the operation. After a time this sensation becomes less pronounced but does not disappear. Immediately after section, painful stimuli on the contralateral side are not appreciated. After approximately two weeks painful stimuli (pinprick, cold and heat) give rise to a peculiar disagreeable feeling in the part stimulated. The sensation is not painful but annoying, as it is more unpleasant than pinprick on the normal side. Localization of touch, two point discrimination, vibratory sensibility, position sense and joint sense are practically normal. One or two days after operation hemianopsia contralateral to the lesion is usually demonstrated. Within a week the visual acuity usually returns to normal. Subjectively there were no auditory abnormalities, but audiometer tests revealed impaired appreciation of high tones by the ear contralateral to the lesion. For about a month after operation the leg contralateral to the lesion is not as strong or agile as the ipsilateral leg. The strength of the other extremities is normal. No ataxia has been demonstrated. Disturbances of bladder function were not observed. Incontinence of the bladder occurred in 1 patient who was confused and stuporous from cerebral softening precipitated by manipulation of the brain, renal failure and infection of the bladder. No statement regarding libido can be made as yet.

Thymoma Removal in Myasthenia Gravis—Judging from available reports, Turnbull believes that the results of thymectomy appear more promising than those of removing a thymic tumor. To arrive at any conclusions regarding the treatment of myasthenia gravis it is necessary to distinguish sharply between these operations. When more cases of the successful removal of a thymic tumor are recorded, the pathologic type of tumor will probably be found to be important. Of the 5 recorded cases in which the removal of a thymic tumor was successful (including the author's case) dramatic and immediate cure resulted only in the case in which a carcinoma was present. In 2 the tumor was a lymphosarcoma, and in both it is questionable whether operation caused improvement or prolonged a remission, in 1 the operation probably had no effect on the disease, as the tumor that was removed was devoid of anything but debris and fibrous tissue, and in the author's case removal of a lymphosarcoma had no appreciable effect on the myasthenia gravis.

Experimental Gas Gangrene—Sandusky and Meleney produced wounds in anesthetized guinea pigs and contaminated them with certain of the clostridia associated with gas gangrene in human beings. Subsequently the wounds were treated locally with sulfanilamide, sulfadiazine, sulfathiazole, sodium sulfadiazine, sodium sulfathiazole, gramicidin and zinc peroxide. When used in wounds within two hours of production and contamination with *Clostridium welchii* or *Clostridium septicum*, sulfanilamide, sulfadiazine, sulfathiazole and the sodium salts of the latter two were effective in preventing the death of animals from gas gangrene. The effectiveness of zinc peroxide in such wounds was not convincing. Zinc peroxide was effective in producing a slight but statistically significant reduction in mortality from gas gangrene in animals whose wounds were contaminated with *Clostridium novyi*. Sodium sulfathiazole approached zinc peroxide in effectiveness, but the reduction in mortality was not statistically significant. The other sulfonamide compounds failed completely in *Cl. novyi* contaminated wounds. None of the agents were effective in preventing death from gas gangrene in animals whose wounds were contaminated with *Clostridium sordelli*. Yet sulfadiazine, sulfathiazole and their sodium salts significantly delayed death. In animals with *Cl. welchii* contaminated wounds debridement, irrigation of the wounds and chemotherapy were of significantly greater value than chemotherapy alone. Debridement and irrigation without chemotherapy gave results similar to those obtained in untreated controls. In general sulfadiazine, sulfathiazole and their sodium salts were more effective in preventing experimental gas gangrene than was sulfanilamide. Since the results have a direct clinical application there should be a consensus among investigators in this field so that the experimental methods, the contaminating organisms (their dosage and method of administration) and the treatment to be instituted could be standardized. The discrepancies in the results so far obtained in experimental gas gangrene indicate that further studies are imperative before the newer chemotherapeutic agents can be evaluated properly.

Prefrontal Lobotomy—Freeman and Watts state that now the problems in prefrontal lobotomy are beyond their first stage of the hit or miss production of destructive lesions of the frontal lobes and then waiting to see what the effect will be. With continued study for six years they have developed an operative technique that has certain merits of precision. They have followed all their 136 patients with periodic surveys so that they can now give the following conclusions: 1 Prefrontal lobotomy interrupts the connection between the frontal lobe and the thalamus, thereby reducing the subjective emotional reactions of the patient. This loss of painful self-consciousness in the psychotic patient is followed by reintegration of the personality with the idealistic activities directed outward. 2 Intelligence is unharmed but its application subjectively to the interplay of social and personal influences is diminished and in some patients results in indolence and lack of tact. 3 Many patients are able to reach their prepsychotic level of occupational adjustment, some even exceed it. 4 Failures are due to (1) inadequate operation which may be corrected by a secondary more complete lobotomy, (2) a too extensive operation, (3) inadequate evaluation of the aggressive traits of the patient previous to the development of his psychosis and (4) emotional deterioration. 5 Old people whose lives are a burden to themselves by reason of psychosis are particularly good subjects for prefrontal lobotomy because of the serenity of disposition that follows the operation. 6 Best results are obtained in obsessive tension states, good results in involutional depression, fair results in schizophrenia and poor results in alcoholism. Prefrontal lobotomy is comparable in its effects with the neurosurgical operations for relief of pain, only in these cases it is mental pain that is relieved.

Treatment of Burns with Sulfadiazine Spray—Coloviras and his co-workers have treated the burns of 8 patients with a spray of sulfadiazine in triethanolamine and plasma and other supportive measures. This method, reported by Pickrell in 1941, possesses several advantages over previous methods. The resulting eschar allows the patient to be out of bed much more quickly than do those of other methods, because cracking is considerably decreased as the eschar is soft and pliable yet strong enough to withstand the strain of movement. It does not bind granulating surfaces tightly if at all, causing constriction as do other eschars because it fits more loosely on the

wounded surface being a hardening of the vehicle rather than a precipitation of surface proteins. The spray is of definite value in combating gram positive and gram negative organisms commonly infecting burned surfaces without damaging tissues. Burns of the face can be managed with this treatment. Pain was relieved within fifteen minutes of treatment. The eschar can be adjusted to any depth by varying the amount of spray applied. The disadvantages of the method are that the eschar is formed relatively slowly, toxic reactions with the use of the spray on large areas of the body are possible and grafting is impeded.

Removal of Sacral Parasitic Fetus—The successful removal of a large parasitic fetus from a 7 month boy is reported by Gray. The mass, attached to the coccygeal region by a wide pedicle which seemed to displace the anus anteriorly from the coccyx, was removed twenty-four hours after birth. Prior to operation a roentgenogram revealed that there was no skeletal connection between the baby and the parasitic fetus. When the tumor was completely removed and hemostasis secured, it became apparent that closure would have to be transverse in order to push the rectum up into the hollow of the sacrum and to approximate the anus closer to the coccyx in the normal relationship. When interrupted plain catgut sutures of the subcutaneous and fascial tissues of the upper and lower margins of the wound, after a gram of sulfathiazole powder was sprinkled into the large raw area were tied it was found that the coccyx had to be removed so that the cutaneous margins could be approximated without tension. Another 0.5 Gm of sulfathiazole was sprinkled in the wound and the skin was closed with interrupted silk sutures. Seventy five cc of compatible whole blood was given intravenously during operation. The wound healed by first intention and the sutures were removed in eight days. The baby's general condition was excellent and he was discharged three weeks after operation. The child undoubtedly owes his life to the fact that labor was induced at seven months because of the mother's toxemia, and to the fact that the tumor did not communicate with any vital structure of the infant. The tumor, hardened in formaldehyde for a week on section revealed cerebral tissue, well developed convolutions of an almost perfect hemisphere, a ventricle, choroid plexus within the hemisphere, bronchi, pulmonary tissue, ciliated epithelium underlain by submucous glands, vascular structures, high columnar epithelium tending to form papillary infoldings simulating gastrointestinal tract, skeletal development, marrow and cartilage. Other microscopic sections showed cerebral cortex and subcortical white matter together with choroid plexus structure and dura mater, fat, voluntary and involuntary muscular fibers, lung, renal tubules, typical lymph nodes, vascular structures and one ganglion composed of typical ganglion cells and neurons surrounded by a fibrous tissue capsule in well differentiated form. The skin covering the tumor was typical epidermis including coil glands, hair shafts and sebaceous glands. The maternal grandmother of the baby was a twin and had sisters who were twins. Also the paternal grandmother had maternal and paternal twin cousins.

Modern Conception and Treatment of Frostbite—Bigelow states that rubbing or massaging in frostbite and trench foot damages the skin and increases tissue reaction. Some means to increase the blood flow to the affected part before secondary reactions of thrombosis and arterial change set in may reverse the process of stasis and supply oxygen to meet the demands of a locally increased metabolism. A slow rate of thawing minimizes the metabolic demands of the tissue. The use of heparin for preventing thrombosis suggests itself. Sympathetic nerve anesthesia or extirpation of sympathetic ganglions would counteract spasm and also supply the required increase in blood flow. From the personal account of a North Greenland explorer, downward massage of the limb above the frozen limbs of 3 members of this party, carried out in a cold room, resulted in slow but complete recovery. If such massage relieves arterial spasm and forces arterial blood into the extremity, its rationale as a first aid measure is good. To insure slow thawing, Kreyberg suggests keeping a small ward cooled to between room temperature and freezing. A more beneficial type of treatment may be local refrigeration of the elevated extremity with

heat to the remainder of the body. This would aid in counteracting shock and would produce a reflex vasodilatation in the affected limb. Refrigeration should be continued for one to several days, depending on the severity of the lesion. Controlled thawing may be accompanied by "the application of cold water at 10 to 15 C." Cooling relieves some of the pain that accompanies thawing.

Conception of Neuralgic Chest Pain—Among 341 consecutive cases referred to an army medical consulting clinic 100 men complained of chest pain. In 53 the pain was the major if not the chief, complaint. The conception that Heaton has of these pains is that they are pains of essentially similar nature, sharing a common mechanism of production, though this mechanism may be operated by different factors in different cases. The pain is more deserving of a name than are its initiating factors which determine its occurrence and location, since these factors are multiple and not necessarily themselves of the nature of progressive organic disease. Two names in use are sufficiently inclusive "neuralgia" and "causalgia." The first term is preferred, as the latter has a rather limited connotation at present. If an explanation of this chest pain is attempted it must explain its increased frequency in emotionally unstable persons, in whom it may be provoked by excitement alone, its association with organic thoracic disease, its occasional occurrence without evident emotional instability and without evident intrathoracic disease (intercostal neuralgia) and the effect of movement in provoking pain. The same pain may occur in the apparent absence of all these conditions and any of these conditions may be present without the chest pain. The pain in "chronic pleuritis," "effort syndrome" and some cases of organic disease of the heart and lungs cannot be differentiated in character from neuralgic pain. Such pain is commonly misdiagnosed as 'pleurisy' or 'heart disease,' and when the same type of pain occurs in the abdomen as 'appendicitis' or 'kidney trouble.' The prognosis varies greatly, being worst among the chronically psychoneurotic. The pain on rare occasions is moderately disabling.

Typhoid Due to Infected Cheese—From December 1939 to March 1940 three outbreaks of typhoid apparently due to cheese occurred in the province of Manitoba. Although typhoid bacilli were not recovered from the cheese, Bowman presents epidemiologic evidence which suggests that the three outbreaks were probably caused by infected cheese. The evidence submitted suggests that cheese made from raw milk may constitute a serious hazard in transmitting typhoid unless such cheese is aged for an adequate period. (The Army will not buy cheese until it has been aged for at least three months.) Milk produced for cheese making should be supervised and controlled as rigidly as that for liquid consumption. Either pasteurization of milk or adequate aging of cheese should be insisted on. As carriers with no history of illness may be common, all reasonable precautions must be taken to avert the transmission of typhoid bacilli.

Experimental Human Vaginal Trichomoniasis—The cooperation of 80 pregnant patients made it possible for Hesselstine, Wolters and Campbell to study the effect of inoculating the Trussell-Plass strain of trichomonads. Seventy received the unaltered culture, while 10 received only the filtrate portion of the culture. The twenty-four to forty-eight hour cultures were implanted in the vagina. Fifty-three patients had vaginal smear controls, while the remaining 17 had only clinical observation. No positive reaction for vaginal trichomoniasis developed in the latter group. Seven of the former group had positive reactions and in 2 others trichomoniasis developed after delivery, yet the smears of these 2 were negative prior to parturition. The general trend was for the trichomonads to disappear in the course of a few to several days. Only 3 of the 7 patients had symptoms, while 6 of the 7 had a typical discharge on examination. Only 2 received treatment, the rest improved without it. Six of the 7 had a bacterial flora (judged by smear) which is supposed to be more favorable for the growth of the vaginal trichomonads than the theoretical normal. The literature on the vaginal tetratrichomonads and the present data are deficient to prove the presence or absence of immunity in those women who did not become experimentally infected. Special studies must be made to solve this problem.

Scarlatinal Encephalomyelitis—Because of the rarity of diffuse encephalomyelitis in the course of scarlet fever Winkelman reports such an occurrence in a Negro girl of 9. The diffuse inflammation involved the brain and the cord and showed no special predilection for either the gray or the white matter. The cerebral symptoms developed seven days after the onset of scarlatina. There was clinical evidence of widespread involvement of the entire brain stem and spinal cord. At necropsy a type of perivascular encephalomyelitis resembling that seen in measles, after vaccination and the other known virus infections

was observed. The conclusion is reached that the complications of the central nervous system were not the result of the 'scarlatinal organism itself' but developed from the release by the streptococcus of a virus lying dormant within the system. Clinically the condition was different from the usual mild neurologic complications seen infrequently in scarlet fever. The changes within the central nervous system were so intense and widespread that recovery was precluded.

Central Nervous System in Tetanus—Baker studied tissues from 12 cases of human tetanus and gives a composite description of the changes in the central nervous system in such cases. The study reveals that the tetanus toxin does have an affinity for the central nervous system and that if the illness is sufficiently prolonged it will produce structural damage to its tissues. Functional impairment of the nervous elements occurs in almost every case regardless of the duration of the disease but in the more rapidly fatal ones the affliction is not of sufficient duration for such changes to become anatomically apparent. If death occurs before the fifth day of the illness few alterations are visible. The nerve cells are first to become involved, the damage is irregular and a swelling and perinuclear chromatolysis are present. The anterior horn cells are rarely severely involved and certainly much less affected than the nerve cells of the cerebral cortex or the cells of the cranial nerve nuclei. Even in the presence of severe cortical damage the anterior horn cells usually appear intact. If the illness lasts more than five days perivascular areas of demyelination and gliosis occur. These lesions are widely disseminated within the cerebral hemispheres. In prolonged disease they often result in large confluent areas of tissue destruction. Death is generally believed to result from exhaustion circulatory failure and asphyxia due to spasm of the glottis diaphragm and intercostal muscles during the convulsions. Extensive pathologic alterations may occur within the medulla. Therefore certain cases of tetanus must terminate fatally because of structural damage to the medullary centers with secondary cardiac or respiratory failure. The possibility of such cerebral involvement in tetanus must force one to a guarded prognosis in every case. The consistent perivascular distribution of the lesions strengthens the view of a hematogenous spread of the tetanus toxin. This widespread scattering of the lesions also adds weight to the belief that the toxin is disseminated through the blood stream.

Otitic Meningitis—To evaluate the results of treating otitic meningitis with the sulfonamide drugs, Williams and his co-workers analyzed the 46 cases that they observed during the five years before their advent and the 24 encountered since. In 10 of the first group, fulminating meningitis was associated with acute otitis media, no specific treatment was attempted other than spinal drainage. These 10 patients died. The 7 in whom otitic meningitis occurred subsequent to mastoidectomy for acute or chronic disease of the temporal bone also died. Two of the 9 patients in whom otitic meningitis was diagnosed before mastoidectomy recovered. Hemolytic streptococci were cultured from the spinal fluid of 6, type III pneumococci from 2 and type I pneumococci from 1. In the last case antipneumococcus serum was without demonstrable benefit. In the remaining 20, examination disclosed increased pressure of the cerebrospinal fluid, leukocytosis and neurologic signs of meningitis, microorganisms could not be demonstrated. In 12 of the 20 there was evidence of petrositis. The leukocyte count of the cerebrospinal fluid in 5 of the 12 ranged from 200 to 6,000 per cubic millimeter. These 5 patients recovered. The cerebrospinal fluid of 7 contained less than 100 polymorphonuclear leukocytes. 5 recovered and 2 died. In the remaining 8 mastoidectomy was performed, 4 recovered and 1 died of a cerebellar abscess, 2 of postoperative thrombosis of the cavernous sinus and 1 of a subdural abscess over the anterior surface of the cerebellum. The 24 patients treated during the last five years represent a 48 per cent reduction in the number encountered over the previous five years. This reduction becomes even more striking as the number of patients hospitalized during this time for diseases of the middle ear and sinuses was actually increased. The most likely explanation for the change is that the routine use of sulfonamides has prevented the development of meningitis. Fulminating meningitis occurred in 6 of the 24, 4 died and 2 recovered. These patients were seen soon after the advent of sulfonamide therapy and illustrate the danger of inadequate doses. In 3 of the 24 otitic meningitis, with petrositis in 2, developed after mastoidectomy, 2 died. The 1 who recovered did so after a prolonged use of sulfapyridine without operation in spite of the petrositis and a severe diabetes. In 11, otitic meningitis was diagnosed preoperatively, and treatment consisted of chemotherapy and surgical drainage of the focus of infection in the temporal bone. Two of 4 patients suffering from the pneumococcal infections recovered, only 4 of the 6 with meningitis due to hemolytic streptococci recovered after adequate chemotherapy and surgical treatment, and 1 patient with green producing streptococci died in spite of high concentrations of sulfapyridine and surgical treatment of an apical petrositis associated with epidural abscesses. The remaining 4 patients had definite meningitis but culture of the cerebrospinal fluid was negative. Two of these patients died, 1 of thrombophlebitis of the cavernous sinus and 1 of cerebrospinal meningitis. The other 2 recovered after intracapsular exploration and drainage of the petrous apex combined with adequate chemotherapy before and after operation. Among these 24 patients of the second group there were 4 for whom chemotherapy was used entirely too late and to 4 others the amounts given were inadequate. Therefore, as only 16 of the 24 patients received adequate chemotherapy the recovery rate for these 16 is 69 per cent as compared to 35 per cent for the 46 in the first group. Therefore, with chemotherapy and drainage, the recovery rate of adequately treated patients has been doubled during the last five years.

Coronary Sclerosis—Barnes and Pruitt believe that special attention in heart disease, particularly in the diagnosis of coronary sclerosis, without an extensive general knowledge of internal medicine is fallacious. Coronary disease may infringe on and have to be distinguished from diseases affecting numerous adjacent organs. A discriminating history is indispensable in differential diagnosis, failure of which may lead to unwarranted and extremely hazardous surgical intervention when the pain of coronary thrombosis is situated in the upper portion of the abdomen, or the patient may be deprived of a much needed operation if lesions of the upper portion of the abdomen producing pain referred to the thorax are regarded as of cardiac origin. The diagnosis of angina pectoris is based on the history of symptoms and not on physical and/or laboratory data.

Hemolytic Transfusion Reactions Due to Rh Factor

—Diamond discusses the transfusion reactions that occurred in 10 recipients who were given blood compatible for blood groups but incompatible as to the Rh factor that is the donor's blood was Rh positive and the recipient's blood lacked the Rh factor and had a means of isoimmunization previously, leading to the development of an anti Rh agglutinin. In another patient an anti Rh agglutinin was demonstrated early and a transfusion reaction was avoided. Isoimmunization occurred in some patients as the result of previous transfusions with Rh positive blood, in others because of a fetus having Rh positive blood cells. In still another patient an anti Rh agglutinin of natural origin seemed to be present. Mixtures of the recipient's Rh negative cells and the donor's Rh positive cells were observed in the blood of 3 patients soon after the hemolytic transfusion reaction. This necessitated care in interpreting the test for Rh positive cell agglutination. In 2 women of childbearing age isoimmunization to the Rh factor developed through the use of Rh positive blood for transfusion, and it seemed to have been the direct cause of the severe fetal erythroblastosis in the infant of a subsequent pregnancy. Following the hemolytic reaction, the use of Rh negative blood for subsequent transfusions caused no further difficulties.

Cancer of Prostate—The results that Chute and Willetts obtained in 37 patients with carcinoma of the prostate treated by castration and/or estrogen are reported. In 33, carcinoma of the prostate was proved by microscopic study and in 4 there was convincing clinical evidence. Two patients were treated with castration only, 8 with stilbestrol (diethylstilbestrol or diethylstilbestrol dipropionate) only and 27 with castration and stilbestrol. The effect of stilbestrol was equal to that of castration and stilbestrol, but the effect of stilbestrol alone lasted only during its administration. The general results were extremely satisfactory, and only 1 patient seemed to obtain no benefit. Three patients died during the year of the study. The effect, consisting in effective and lasting relief from the pain of metastasis, improvement in appetite, weight and strength, a feeling of well being and decrease in the size and softening of the prostate, was rapid. In 9 of 13 with urinary retention treated with orchietomy and stilbestrol, the size of the obstructing prostate was so reduced that the ability to void was reestablished. If the preoperative level of the acid phosphatase

was above normal it fell rapidly after castration and was still further reduced by stilbestrol. The alkaline phosphatase usually rose soon following castration whether or not stilbestrol was used. The 17-ketosteroids were lowered in most cases after orchietomy. In 5 patients with bony metastasis demonstrable roentgenologically, followed for more than six months the metastasis was apparently progressing as usual. After castration libido and the power of erection disappeared but there were no other harmful effects. No dangerous or harmful effects followed stilbestrol therapy, but there were minor unpleasant effects which disappeared if the drug was discontinued or the dose decreased.

Clinicopathologic Study of Rheumatic Fever—An analysis by Bruno and Engelhardt of the discharge diagnosis of 187,987 patients from January 1939 through 1941 revealed 150 cases of acute rheumatic fever, an incidence of 0.08 per cent. Sixty six patients were Negroes and 86 were white persons. During the three years of the study there were 725 instances of rheumatic heart disease, 51 per cent of the patients were white and 49 per cent Negroes. There was no appreciable racial difference in active and inactive rheumatic heart disease. The data obtained from 16,121 necropsies revealed 102 cases of rheumatic heart disease, 46 of the patients were white and 56 were Negroes. The study suggests that Negro patients suffering from rheumatic heart disease tend to die at an earlier age than do white patients.

Noncarcinomatous Ulcerations of Cervix—The postirradiation complications involving the bladder and rectum, which are now recognized and frequently anticipated that were observed in 4 of the 99 patients with carcinoma of the cervix that Jacob, Johnston and Gross treated, occurred months or years after the radiation therapy and were caused by occlusive vascular changes. Difficulty is sometimes experienced in differentiating the postirradiation necrosis or ulceration from a recurrence or an extension of the malignant growth. A similar postirradiation ulceration in the cervix itself caused by vascular occlusion also would cause considerable diagnostic difficulty. The lesions of each of the 4 patients developed at or near the site of the original carcinoma suggesting a recurrence. In 1 this impression was so strong that, pending the biopsy report, a hopeless prognosis was considered and in 2 roentgen treatments were begun and then discontinued when microscopic study failed to reveal carcinoma. The classic vascular occlusive changes secondary to radiation were demonstrable in sections of the lesions from each of the patients. The vascular changes caused infarction with the associated necrosis and ulceration. Only microscopic examination of the tissues will disclose the true nature of the suspected lesions.

Tuberculosis of Female Genitalia—Auerbach states that from January 1933 to July 1941 52 cases of tuberculosis involving one or more organs of the female genital tract were revealed at the postmortem examination of 571 females with tuberculosis whose ages varied from 2 to 56 years. The fallopian tubes of 49 were involved the uterus of 29 the ovaries of 15 and the vagina of 2. Tubal tuberculosis was bilateral in 46, the abdominal ends were first and most extensively involved. The tubal tuberculosis was the result of a hematogenous tuberculosis, the hematogenous seedings occurred during a fresh primary complex from a tuberculous extrapulmonary organ or a chronic pulmonary tuberculosis. The size, shape and form of the tubes were not altered in the early stage of the disease, as the process progressed they became thicker and softer and on cross section were almost caseous. Tuberculous peritonitis developed in the 26 with the more extensive involvement. This caused a matting together of the tubes and the surrounding structures. The tuberculous process in the tubes began with the development of foci in the wall which, on perforation into the lumen, spread to the remainder of the tube. The tubes of 3 healed, in 2 with calcification and in 1 with beginning scar formation. In 26 of the 29 the uterine tuberculosis was the result of an intracavitary extension from the tubes, the uterus showed decreasing intensity of the process from the fundus toward the cervix. The cervix was infrequently tuberculous. The size and shape of the uterus were rarely altered even in extensive disease. The tuberculous process was usually limited to the endometrium but sometimes extended into the myometrium. In 3 the tuberculous process was part of a hematogenous dissemination, the foci were present in the wall and were unrelated to a tubal tuberculosis. In ovarian tuberculosis both ovaries were involved as the result of extension from the surrounding structures (perioophoritis). The vagina was infected from the tubes and uterus and contained ulcers and nodules which decreased in intensity from above downward. Primary tuberculosis was not encountered and the author doubts its occurrence.

Two Needle Oxygen Myelography—A method which uses oxygen and employs two needles for the roentgen visualization of the spinal subarachnoid space is described by Munro and Elkins. The method can be used to fill any or all of the space without distortion and as frequently as necessary without affecting later observations. The technique is based on the hydrodynamic laws that govern the substitution of gas for liquid in a closed container. The evening before the patient is given 1 ounce (30 cc) of castor oil by mouth and a soap-suds enema.

The following day he is placed in the lateral position on a tilt top x-ray table with a Bucky-Potter diaphragm. An adjustable webbing sling attached by its free ends to the table and looped about the patient's shoulders keeps him in place when the table is tilted. A low lumbar puncture is performed, followed by puncture at the cephalad level to be filled. If the entire canal is to be visualized, the cephalad needle is placed in the cisterna magna. If the thoracic and lumbar region is to be visualized the cephalad needle is placed at the desired level in the thoracic region. If the lumbar area alone is to be visualized the cephalad needle is placed between the twelfth thoracic and the first lumbar vertebra. Number 18 gage Fremont-Smith needles with three way stopcocks are used for the punctures. After spinal fluid is removed from each needle for protein determinations and cell counts the patient's head is lowered to 25 degrees below horizontal and both needles are opened. Fluid will flow from the cephalad needle and as this occurs, oxygen is slowly injected into the caudal needle. The injection is made from a sterile 50 cc syringe which has been filled from a small oxygen tank. The oxygen must not be injected under pressure. When spinal fluid ceases to flow from the cephalad needle and oxygen appears, both needles are closed. Stereoscopic lateral roentgenograms are now taken of the lumbar and thoracic levels. Oblique views satisfactorily replace the lateral and anteroposterior views in the cervical level. To fill the lumbar area 20 to 30 cc of oxygen has been found sufficient, 40 to 50 cc for the mid-thoracic and lumbar areas and 75 to 100 cc for the entire spinal canal. In the eleven months to January 1942, sixty-nine myelograms have been done by the two needle method on 60 patients. Thirty-seven of the 60 patients did not need surgical intervention. In 9 patients a diagnosis of protrusion of the nucleus pulposus following rupture of an intervertebral disk was made on the evidence of the myelogram and other data. The protruded nucleus was found at operation exactly as visualized on the myelogram. Laminectomy confirmed the two needle myelographic visualization of 1 case each of congenital absence of the sacrum, congenital duplication of the lumbosacral spine and traumatic distorting adhesions and scar formation between the dura and the cervical cord. An exploratory procedure for a ruptured intervertebral disk was carried out on 7 patients in spite of negative two needle myelograms, pathologic changes were not found. The operative observations disagreed with the myelogram in only 2 of the 23 patients operated on. 1 was a patient with a metastatic tumor of the sixth dorsal vertebra and a dynamic block with myelographic evidence of involvement of the spinal meninges at the same level and in 1 the myelogram was interpreted as positive for an extruded nucleus by one and negative by another surgeon. Exploration demonstrated a thin layer of unidentified abnormally placed tissue on the anterior aspect of the low lumbar dura. In 1 case a protruded nucleus was diagnosed and removed at operation without any previous visualization of the subarachnoid space. Thus, in 23 cases the method accurately depicted the spinal subarachnoid space in 20 was useful but not accurate in 2 and was not used in 1.

Left Subphrenic Abscess—The disparity between the mortality of right (35 per cent) and of left (75 per cent) subphrenic abscess at the Mount Sinai Hospital prompts Neuhoef and Schlossmann to consider 33 adequately documented consecutive cases of left subphrenic abscess observed at the hospital since 1928. During the same time 51 cases of right subphrenic abscess were observed. The authors say that the various organs bordering the left subphrenic space, and their mobility, render more complex the problem of diagnosis and treatment of left subphrenic abscess. Left subphrenic abscesses only followed antecedent intra abdominal infections. The almost invariable pathway of spread was by direct extension, and lymphatic dissemination hardly played a role. Rightsided gastroduodenal perforation was an unexpected cause of left subphrenic abscess. Clinical manifestations of left subphrenic abscess usually vague and sparse, often appeared relatively late in the disease. Indirect signs of thoracoabdominal involvement were usually more significant than direct signs of a subphrenic abscess. Conclusive evidence was a raised paretic left diaphragm but this was only occasionally present. Roentgen study of the diaphragm particularly lateral and oblique views is of importance in revealing the position of the diaphragm and the subphrenic shadow of the inflammatory process or abscess. Exploratory aspiration is

often imperative to establish the diagnosis. The study of the roentgenogram should be the chief guide to the site of aspiration. A subphrenic abscess may exist despite repeated negative aspiration, and then an exploratory operation is desirable. A subpleural approach is advocated for abscesses of the 'abdominal' type and a transpleural transdiaphragmatic approach for the 'thoracic' type. A two stage transpleural transdiaphragmatic operation was attended with poor results. A satisfactory one stage operation featuring a double sealing of the free pleura by two tiers of diaphragmatic sutures is described. The inclusion of right and left subphrenic abscess under subphrenic abscess is not desirable because of the difference in etiology, pathogenesis and mortality.

Pulmonary Edema—On the basis of their results with cats in trying to determine why there is pulmonary edema in some patients after thoracic surgery the Gibbons conclude that the edema occurs because of increased capillary blood pressure because of decreased colloid osmotic pressure of the blood plasma or because of an increased permeability of the capillary endothelium. They say that the use of plasma and blood transfusions in thoracic surgery must not be indiscriminate. When the cardiorespiratory function following or during a thoracic operation, has been impaired in any way it seems that when fluids, which tend to remain in the blood stream are given intravenously a certain degree of caution should be exercised and signs of pulmonary edema should be watched for.

Etiology of Riedel's Struma—De Courcy thinks that the true cause of Riedel's struma is a perithyroiditis and that the fibrous growth begins outside rather than inside the thyroid itself. It has always seemed to him that Riedel's struma is a vascular rather than a glandular disease that is, a disease which begins with a perithyroiditis resulting in secondary changes in the gland. The fibrous whorls found about the blood vessels are similar to those described by Goldblatt and his associates which follow partial occlusion of the renal blood vessels. The perithyroiditis with the adherent muscles probably causes a constriction of the thyroid vessels and their superficial tributaries and thus the fibrous changes of Riedel's disease ensue. Two recent case histories and microscopic observations are presented which the author believes, help to clarify his theory.

Antibacterial Action of Disinfectants—The relative bacteriostatic and bactericidal powers of six mercurial disinfectants commonly used for preparing the skin and for the cold "sterilization" of instruments against *Staphylococcus aureus* and *Escherichia coli* were tested by Hoyt, Fisk and Burde. All the mercurials had a relatively high bacteriostatic power but their bactericidal effect was low. Aqueous iodine and zephiran (an antiseptic containing oil of coconut), on the other hand appeared to be highly bactericidal and bacteriostatic.

Prefrontal Leukotomy—McGregor and Crumlie performed prefrontal leukotomy on 6 patients suffering from melancholia, 12 from schizophrenia and 2 from non-systematized delusional insanity. Of these, 3 with melancholia and 2 with schizophrenia have made a complete adjustment and have resumed their former activities. The mortality for the series was 10 per cent: the first death, that of a man aged 53 with melancholia, was caused by bronchopneumonia following secondary cerebral hemorrhage, and the second death, that of a woman aged 32 with schizophrenia, resulted from cerebral softening following ligation of the left internal carotid artery for deep seated cerebral hemorrhage. The bleeding must have occurred at the time of operation, but this was not apparent when the wounds were sutured. The operation offered hope for a return to a more or less normal life in certain selected cases.

Postvaccinal Eruptions—Bloch states that toward the end of May 1942 a patient with unrecognized oriental smallpox arrived in Glasgow on board ship and was removed to a hospital. During the following two months there ensued in and around Glasgow 9 cases directly connected with the ship, 20 shore cases apparently unconnected with the ship or with each other and 4 cases secondary to the latter group. Two of the patients connected with the ship and 6 of the others died. Wide measures of surveillance and vaccination of contacts had been practiced from the outset. Thanks to the enlightened response of the public and to the cooperation of the doctors and the press, about half a million vaccinations were performed during July. Many instances of regional or generalized vaccinal rashes appeared among children and adults. Many of milder and sparse eruptions must have eluded medical observation. However, records are available of 123 regional or generalized postvaccinal eruptions. One of the 123 patients died. Most of the postvaccinal eruptions appeared within seven to eleven days after a well defined positive primary vaccination of children. A regional papular eczema erupted seven weeks after vaccination of an infant. Etiologic observations were negative. Of 98 who had erythematous or urticarial eruptions 37 had papular urticaria and 20 pleomorphic types of erythema multiforme. Though regarded as impetigo bullosa the eruption of a group of patients simulated multiple autoinoculations. No instance was classified as generalized vaccinia. A previously healthy breast fed boy

whose vaccination at 8 weeks was positive died ten days later of exfoliative dermatitis, that is, on the sixth day of illness or the fifth day of the complicating eruption, the complicating disease was regarded as staphylococcal.

Sulfonamides and Experimental Wounds—Hawking describes the therapeutic activity in experimental wounds filled with a sulfonamide paste without more than superficial cleansing and covered by an occlusive dressing for several days. This is the treatment that has been suggested by Gardham in a communication to the War Wounds Committee of the Medical Research Council for the treatment of wounds under the battle conditions of modern warfare. The persistence of the sulfonamide in a wound can be prolonged by incorporating sulfanilamide in an oily medium or by using a less soluble sulfonamide, such as sulfathiazole or sulfapyridine. Therapeutically (i.e., prevention of streptococcal septicemia) the best results were obtained with a preparation of sulfathiazole consisting of micro crystals suspended in saline solution, with sulfanilamide, which is more soluble and more rapidly absorbed better results were obtained with oily than with aqueous preparations. Microscopically the presence of an oil in the wounds caused undesirable tissue reactions. Of the oils tested, cod liver oil was especially injurious in this respect and liquid petrolatum was moderately deleterious, while cottonseed oil was the least harmful. The best preparation was the microcrystalline preparation of sulfathiazole, which was also the most effective therapeutically. Judging by reports from forces in the Middle East, the sulfonamide dressing of a wound is inferior to excision, but since many exigencies of war render surgical operations impracticable, dressing the wounds with a semifluid sulfonamide preparation is advantageous in restraining bacterial growth until more adequate treatment is feasible in these circumstances the best preparation to use is the microcrystalline suspension of sulfathiazole or, failing that, an aqueous preparation of sulfanilamide.

Gastric and Duodenal Ulcers in South Australia—The data from 5,000 South Australian postmortem examinations that Cleland presents reveal that gastric ulcers greatly preponderated over duodenal ulcers, whether only actual ulcers found at necropsy or scars of healed ulcers were considered. There were 110 gastric to 70 duodenal ulcers, or, if the scars are added, 123 gastric to 84 duodenal ulcers. For each five year period during the twenty-two years during which these necropsies were performed the number of gastric ulcers exceeded that of duodenal ulcers. There has been no change in the relative incidence over these years. In persons less than 50 years of age the incidence of gastric and duodenal ulcers was about equal, but after this age there was a rapid increase in the incidence of gastric ulcers. There was a preponderance of peptic ulcers in men: 150 open ulcers in men to only 30 in women. The sex ratio of gastric ulcers is about 4 men to 1 woman and that of duodenal ulcers is about 7 men to 1 woman. The tabulated results show that the death of 58 of the 110 subjects with gastric ulcer was the result of the condition, in 23 deaths was directly or indirectly due to hemorrhage, in 20 to the more immediate effects of rupture, 4 died from subphrenic or other peritoneal abscesses, 6 after gastrectomy or gastroenterostomy, 1 from massive pulmonary embolism, and in 4 instances death was due to the ulcer but the exact cause was not tabulated. Forty-two of the 70 with duodenal ulcer died as a result of the condition, 12 from hemorrhage or its effects, 22 from the more

immediate effects of rupture, 4 from subphrenic or peritoneal abscesses, death followed gastroenterostomy in 3 and in 1 the exact cause was not tabulated. No pathologic lesion occurred in other parts of the body, with the doubtful exception of hydatid cysts with sufficient frequency to be likely to be connected with the etiology of peptic ulcers. Any possible connection of the hydatid cysts, apart from anaphylactic reactions, would probably consist in injury to the mucosa during the passage through it of the hexacanth embryo.

*Use of Prostigmine in Treatment of Glaucoma. Jenny Kull—p. 23

Prostigmine in Treatment of Glaucoma—Kull demonstrates that prostigmine causes in the normal rabbit eye a rise in pressure followed by a decrease. In patients with glaucoma prostigmine produces a decrease in intraocular pressure. Decrease in pressure can be effected in some patients who previously were treated without success with pilocarpine. The most definite effect was observed with prostigmine in simple chronic glaucoma. Prostigmine is administered to human subjects in solutions from 1 to 3 per cent, in exceptional cases in 5 per cent solutions. The 3 per cent solution is generally well tolerated, whereas the 5 per cent solution frequently causes irritation.

Transmission of Typhus, Laboratory Infections—Löffler and Mooser review the early literature on typhus and its dissemination, giving particular attention to the question of whether it is the bite or the feces of lice which transmit the disease. They consider the following possibilities: (1) scratching, in the course of which feces and intestinal contents of crushed lice are rubbed into the wound, (2) inoculations by the bite of lice by means of the suction apparatus which has been contaminated with feces, (3) introduction of feces into the conjunctiva after the crushing of lice with the fingers (persons infested with lice are in the habit of crushing the lice between the finger nails), (4) inhalation of scattered feces of lice. The authors made their observations on 6 cases of laboratory infection with murine typhus. A percutaneous infection by injury could be excluded in all of them. Droplet infection by virus disseminated in the room must be considered responsible for the infection, so that the respiratory tract is without doubt the port of entry. This was the only possible way in which one of the patients could have been infected, she had never had direct contact with infectious material, she had only once entered the room in which, immediately before, nasal infections of animals had been carried out. The authors suggest that the catarrhal symptoms on the part of the air passages at the onset of the disease is a specific symptom that directs attention to the port of entry. As is usually the fact, the patients required considerable nursing care, but in spite of this there were no further infections. A droplet infection from man to man is not likely. This corresponds to all former observations on the noninfectiousness of deloused patients. Prophylactic vaccination against typhus does not confer complete protection against the disease but probably explains the mild course in 1 of the cases. A survived attack of typhus apparently confers a high resistance even against massive laboratory infections. In view of the fact that many persons who have been vaccinated against typhus contract the disease and that immunized animals can be infected by the nasal route, it is recommended that the personnel of delousing stations be immunized and equipped not only with protective clothing but also with gas masks.

Neurotoxic Action of Sulfonamide Derivatives—Although numerically the nervous disturbances are comparatively small among the secondary effects of the sulfonamide derivatives, they deserve attention because they persist for some time after cessation of the medication. Puhr describes his studies on four groups of 8 leghorn chicks. The tests were made with sulfanilamide, sulfapyridine, sulfanildimethylsulfanilamide and sulfamethylthiazole which were administered by means of an esophageal tube in the form of a 10 per cent suspension that had been stabilized with tragacanth. The daily dose was 0.33 Gm per kilogram of body weight. The treatment was continued for seventy days. The results of these tests are recorded in a table, which reveals that 7 birds died during the treatment and 2 others were sick at the end of the treatment. Sulfanilamide and sulfapyridine had the highest and sulfamethylthiazole the lowest morbidity rates. In the development of the surviving chicks a similar tendency was evident. The neurotoxic manifestations were identical in character but not in degree, first there was contracture of the toes, later a spastic atactic walk and finally the gait was reeling and required the use of the wings. There was considerable emaciation. The birds stopped movements and died within a few days. Necropsies disclosed no gross organic changes. One bird of each group was examined for microscopic changes in the nervous system, particularly the sciatic nerve, with negative results. The spinal cords of 2 chicks were examined and changes were detected so that the author concludes that the anatomic basis of the neurologic symptoms is not a peripheral neuritis but rather a funicular lesion of the spinal cord. He admits, however, that his material was too small to justify conclusions. He failed to produce polyneuritis in pigeons by the administration of sulfamethylthiazole. He emphasizes that the doses he used for the chickens were large and that comparative amounts are never used for human subjects. It is also surprising that the neuritis occasionally seen in human subjects was never developed in chicks or pigeons, in spite of high doses. Thus the animal experiments permit no explanation of the fortunately rare neurotoxic secondary effects, which always seem to have the character of peripheral lesions. The observation of the relatively slight neurotoxic action of sulfamethylthiazole in comparison to other sulfonamide derivatives is in agreement with numerous clinical reports.

*Neurologic Aspects of Insulin Coma. P. Pinto Pupo—p. 5

Diagnosis of Cerebral Cysticercosis During Life of Patients. Cases. D. Lioba Silva—p. 223

Neurologic Aspects of Insulin Coma—Pinto Pupo made observations on 64 patients with schizophrenia in the course of insulin coma. He found that high doses of insulin cause the appearance of neurologic signs that occur with a definite regularity in definite sequence. Neurologic manifestations of insulin shock are uniform, showing differences in intensity but not in quality. In 56 out of 64 cases a type of symptomatology was observed that could be called "classic." Here phenomena of liberation of lower mechanisms were striking. In 5 cases there were observed hypotonia and akinesia. In 2 cases shock did not progress to coma in spite of high doses. In 1 case the clinical picture was dominated by phenomena of hypertonia of the parkinsonian type. Insulin shock permits observation of progressive "dissolution" of nervous functions, thus offering an excellent means of studying nervous physiopathology. The neurologic signs of the insulin shock begin with cortical phenomena followed by those of liberation of the pyramidal tract functions and preceding the extrapyramidal signs. Phenomena of automatic functioning of the brain stem systems, characterized by decerebrate rigidity and ocular disturbances as well as by circulatory, respiratory and thermic symptoms, appear late. Among the most striking phenomena observed is the decerebrate rigidity with its semeiologic characteristics. Decerebrate rigidity takes place in quadriextension of extremities, but the types of flexion of the upper extremities as well as those of extension of the lower extremities are incomplete. Hypertonia of decerebration is an entirely reflex phenomenon. The gradual passage from

the pyramidal to the decerebrate type of rigidity allows their complete separation because of their peculiar semeiologic characteristics. The order of the appearance of pyramidal phenomena of liberation and the lack of correlation among them during insulin shock present a strong argument in favor of the interpretation of these manifestations as depending on different systems. Hyperreflexia, Babinski and similar signs, as well as hypertonia are manifestations of liberation of different systems from their subordination to the pyramidal system. Hypothalamic nervous mechanisms, modifiers of arterial pressure, can work reflexly in consequence of external stimulation when liberated from the subordination to higher centers. This fact may explain the arterial hypertension observed in the first phase of the convulsive, epileptic or metrazol crisis.

Lung in Whooping Cough.—Among pathognomonic auscultatory signs of whooping cough Pospischill considers fine and moderately coarse rales at the bases during the early stage of the disease and coarse rales which can be heard in larger areas of both lungs as the lesions become diffuse. In the advanced cases only coarse rales are heard. Parra reports his observations on 240 cases, which he classifies into two groups. The first group comprises 103 cases all of which present some deviation from the usual course of the disease such as elevation of temperature, alteration in the usual blood picture of whooping cough, change in the respiratory rhythm and appearance of areas of dulness. This group also included patients with a positive tuberculin test although an active tuberculous process had not been established. There were patients in this group with roentgenologic and clinical signs of bronchopneumonia or pneumonia. Many other cases, particularly those with a protracted course and mild fever, presented diagnostic problems. The second group comprised 137 cases in which the course of the disease was typical and the tuberculin test was negative. This group was carefully studied, roentgenograms being made every eighth day. Attempt was made to verify Gottche's observations on the lungs of infants with whooping cough and on his necropsies in which he had observed perivascular, interstitial and peribronchial inflammation. Gottche concluded that whooping cough should not be considered as a catarrh of the upper air passages but rather as a chronic interstitial pulmonary inflammation. On the basis of his own studies Parra reaches the following conclusions: 1. The clinical signs described by Pospischill as characteristic for the whooping cough lung were observed in 50 per cent of the cases particularly in the mild cases. 2. The picture described by Gottche was encountered in only 3. 3. Hilitis and cord shaped shadows were observed in 30 per cent. 4. In 67 per cent the roentgen appearance was extremely difficult to differentiate. 5. The roentgenograms were not indicative of the intensity of the disease process. 6. Roentgenologic appearances may persist for some time after the disease has run its course.

Hemlock Poisoning in Four Children.—Montañes del Olmo reports observations on 4 children of the ages between 5 and 9 years who had eaten roots of poison hemlock (*Conium maculatum*) because they resembled carrots. When seen eight hours later the children were delirious and their pupils showed maximal dilatation and failure to react to light. The pulse was extremely rapid. Aspiration and washing of the stomach yielded clean fluid. Treatment consisted in administration of a solution of sodium sulfate, Hayem's serum and camphor liniment. All children recovered.

Hypertrophic Cervical Meningitis of Tuberculous Origin. R. Matte—p. 768

Sulfonamide Therapy in Infants.—Del Carril and his collaborators stress that in order to obtain best results with sulfonamides the treatment must be early, intense and limited. Among 52 cases of bronchopulmonary disease the authors record thirty successes and twenty-two failures. They regard these figures as encouraging, particularly because this group included a number of cases of bronchopneumonia in which sulfonamides are of little value. They call particular attention to the frequency of relapses when the sulfonamide medication is discontinued a few hours after the fall in temperature. They insist that medication should be continued for from thirty-six to forty-eight hours longer in order to provide time for the absorption of the pulmonary focus and the stimulation of the defense powers. In pulmonary abscess sulfathiazole proved unsatisfactory. Surgical treatment is here irreplaceable. Sulfonamide treatment has reduced the high mortality of purulent meningitis in infants. In pneumococcal meningitis the mortality was 100 per cent before the sulfonamide era but of the 23 patients with this type treated by the authors with sulfapyridine 7 survived. Of 5 patients with meningococcal meningitis 3 were cured and 2 died but all 3 with influenza meningitis died. In erysipelas of infants sulfanilamide proved highly successful. Of the 20 patients, some of whom were gravely ill, only 2 died, 1 of these had bronchopneumonia as a complication and the other was a weak prematurely born infant. In 11 cases of acute enterocolitis in which the authors employed sulfaguanidine the results were more prompt the earlier the treatment was instituted.

Glycogenosis in Child of Twenty Months.—Ortiz Ramos and Perez Martinez present the history of a child aged 20 months with symptoms of glycogenosis (von Gierke's disease). The liver was enormously enlarged. The child had convulsions early in the morning and hypoglycemia before breakfast. The child was extremely sensitive to insulin. Injection of epinephrine did not affect the blood sugar. The urine contained sugar and acetone and the blood sugar curve was of diabetoid type. The authors agree with Jimenez Diaz that glycogenosis is caused by an insufficiency in the secretory functions of the anterior pituitary, the growth hormone and the insulin antagonistic hormone being chiefly concerned. It is assumed that an embryonal condition of the liver exists and that a hereditary predisposition plays a part.

Growth Promoting Nonthiamine Factor in Liver Extract.—In the course of studies on the biologic value of various legumes, particularly chick peas (*Lathyrus sativus*), Jimenez Diaz and Vivanco observed that rats fed exclusively on chick peas exhibited retarded growth. The addition of an animal protein, even of low biologic value, such as gelatin, was found to normalize the growth curve. The authors experimented with the addition of liver extracts and of various vitamins to an exclusive chick pea diet. They found that deproteinized liver contains a thermolabile factor which differs from vitamin B₁ and is capable of normalizing the growth of rats fed with chick peas. Since the same growth stimulus can be produced with animal proteins (gelatin or casein) this factor is assumed to promote the utilization of vegetable proteins in the intestine of rats.

Book Notices

Changes in the Knee Joint at Various Ages With Particular Reference to the Nature and Development of Degenerative Joint Disease By Granville A. Bennett M.D. Associate Professor of Pathology Harvard Medical School Boston Hans Valne M.D. Research Fellow in Medicine Harvard Medical School and Walter Bauer M.D. Associate Professor in Medicine Harvard Medical School Cloth Price \$2.50 Pp 97, with 9 illustrations and 31 plates New York Commonwealth Fund London Oxford University Press 1942

The authors report a study of knee joints of 63 persons ranging in age from 1 month to 90 years, removed post mortem or by amputation. The investigation was made on material taken only from patients without a record or physical findings of joint disease and was undertaken primarily to establish a norm for degenerative changes seen in these joints with advancing age. Other factors, such as excessive trauma and associated specific joint disease were thus ruled out as possible agents in the pathogenesis of the lesions described.

Complete macroscopic, microscopic and x-ray studies were made of all joints. Detailed microscopic examination of weight bearing, non-weight bearing, contacting and noncontacting, as well as the marginal areas of the joint surfaces with reference to osteophyte formation were made. Changes in the menisci, synovia and blood vessels were correlated with the changes noted in the cartilaginous and bony components of the joints.

The material is arbitrarily divided according to decades of life, and the changes are recorded for each ten year period from the first to the tenth. Macroscopic and microscopic changes in the articular surfaces and menisci were first noted in the second decade and became progressively more apparent after maturity. After 15 years of age and subsidence of growth activity, increased prominence of the articular margin at the synovial junction was first noted, although obvious x-ray evidence of marginal proliferation and osteophyte formation was not noted until the seventh and eighth decades.

The minimal changes demonstrable by x-ray examination in all cases were never consistent with the pronounced degree of macroscopic and microscopic degeneration seen in each respective decade. Degenerative changes in the menisci followed closely those of the articular cartilage, whereas the synovia remained relatively unaltered throughout. No evidence of any but incidental association between arteriosclerotic changes in the vessels and joint degeneration was noted.

The section of descriptive morphology is followed by an analytical interpretation of the authors' findings in the light of work of others, and a subsequent section on various concepts of the genesis of the joint changes is likewise approached from a historical point of view. With regard to the pathogenesis of osteophyte formation, the authors suggest that the result of loss of articular cartilage substance and elasticity leads to increased traction on the peripheral joint margins with weight bearing. The resulting functional stress plus other nonmechanical factors lead to hypertrophy and hyperplasia of the tissues in these regions.

The final chapter reviews critically the theories of etiology of degenerative joint disease and suggests possibilities as to future lines of investigation. The authors conclude not only that the problem deals with processes of tissue aging in general but that articular surfaces are subject to mechanical and biologic handicaps quite distinct from other tissues which predispose these structures to early and progressive senescence.

The monograph furnishes a comprehensive, critical review of the literature and current thought regarding degenerative or hypertrophic arthritis and provides a valuable working volume for those interested in the fundamental problems and pathology of joint disease.

The Modern Treatment of Venereal Diseases By E. T. Burke D.S.O. M.B. Ch.B. Cloth Price 12s 6d Pp 105 with 6 illustrations London John Bale Medical Publications Limited [1942]

As indicated in the foreword by Dr W. Allen Daley, this was the last manuscript completed by Dr Burke before his death. In such a small volume it is almost impossible to do more than touch the most salient points in the treatment of syphilis. In fact the author constantly refers the reader to his larger volume "Venereal Diseases" (London, H. K. Lewis & Co., Ltd., 1940).

He still believes in the use of Zittmann's decoction in certain cases of malignant syphilis "in refractory, relapsing and drug inert patients." He thinks the effects are due to the presence of two saponins in the sarsaparilla root in the compound. He prefers liposoluble bismuth and likes no oral bismuth compounds. He thinks there is a place for acetarsol (acetarsone) for adults (sailors and travelers, long distance lorry drivers and others). He considers mapharside (mapharsen) inferior and causative of disquietingly high incidence of toxic effects. This certainly is not true of our American product. He is fearful of sulfarsphenamine and bismarsen because of a tendency to blood dyscrasias and exfoliative dermatitis; he prefers neoarsphenamine.

His criteria of cure are as follows: 1. Negative Wassermann and Kahn tests at intervals of thirteen weeks for two years after treatment. 2. Absence of clinical and radiologic evidence of syphilis. 3. Negative cerebrospinal fluid at the beginning during and at the end of the observation period.

Burke evaluates treatment in terms of therapeutic units for various arsenicals and bismuth compounds and considers that an efficiency index of more than 60 assures the patient with an early syphilis of a cure. This is assured by the formula $E.I. = \frac{\text{Therapeutic units} \times 100}{\text{Weeks}}$. To be sure this method of evaluation

of therapy may be worth while, but it is rather cumbersome. His data with it are quite similar in end results to those in American clinics. He is a firm believer in the use of continuous therapy for early syphilis, using alternating courses of arsenicals and bismuth compounds. In fact, he was the first man in England to accept this method of therapy. In chronic syphilis he is not so sure of the value of his efficiency index. Certainly it shows that a patient receiving less than an index of 60 could not hope for a cure. He is a firm believer in the use of intravenous iodides in late syphilis and central nervous system syphilis—here along with fever therapy, trypanamide and liposoluble bismuth. In congenital syphilis we are surprised to note that he advises intravenous iodides for interstitial keratitis. The Cooperative Group, Klauder and others have called attention to the irritating effects of this agent in such a situation. No mention is made of fever therapy for it.

The remainder of the book is devoted to gonorrhea and so on. Only a few paragraphs are devoted to chancroids and only a single paragraph to venereal lymphogranuloma which is even more important and far more crippling.

It is doubted that this small book would be of much value to American readers. It is too compressed. Moreover the English names for antisyphilitic agents would be confusing for the average physician.

It is to be regretted that Dr Burke, a great leader in the fight against venereal diseases in England, is no longer with us.

La digital. Estudio clínico. Técnica del tratamiento. Resultados Por el Doctor Alejandro Garretón Silva profesor titular de la Facultad de medicina de la Universidad de Chile Santiago Cloth Pp 143 with one illustration Santiago Empresa editora Zig Zag S. A. 1942

The author attempts in this small volume to present to his countrymen a fairly complete discussion of the various aspects of digitalis which in his opinion are essential to its intelligent and adequate therapeutic use. After a brief historical introduction he points out that cardiac cases are numerous in Argentina as a justification for the presentation of this succinct discussion. He then discusses the drug digitalis, the chemical structure of the contents of the leaf, the preparations and the choice of the most useful ones. Along with this he lays much emphasis quite rightly on biologic assay and proceeds to discuss briefly the mechanism of its therapeutic and toxic actions and its effect on the electrocardiogram. Turning then to its clinical employment he discusses this phase under twelve separate headings and then goes on to chapter four, in which he presents in moderate detail the questions of dosage, the practical use of the drug under various conditions, its maintenance dose and its use as a means of preventing decompensation, along with its contraindications, and he further mentions agents which he considers to be contraindicated in the presence of digitalis administration, as well as those medications which are useful as auxiliaries to digitalis in the treatment of the cardiopathic patient. He closes with a bibliography of about seven pages which, while helpful, is little more than briefly representative of the more important

work of the last two decades. In general his recommendations are perhaps a little on the conservative side. It is evident that the author accepts very largely the influence of American cardiology and pharmacology. Unfortunately he has not supported his statements by personal experiences in the form of case histories or group studies on cases, although he has documented them from the literature. The typography and makeup of the volume are both satisfactory. There is an erratum sheet of eight items which certainly does not represent all of the errata observed in the book. All in all the volume is acceptable and should prove of considerable constructive help to the medical profession in Argentina and perhaps well beyond its borders.

Pathology and Treatment of War Wounds. By Sir Almroth E. Wright M.D. F.R.S. Director of the Inoculation Department and Principal of the Institute of Pathology and Research, St. Mary's Hospital, London. Researches from the Inoculation Department, St. Mary's Hospital. Cloth. Price 21s. Pp. 208 with illustrations. London: William Heinemann Ltd. 1942.

This volume consists of a collection of papers and lectures by Sir Almroth Wright and his associates during World War I. Articles have been selected from the Proceedings of the Royal Society of Medicine of 1915 and the *Lancet* of 1916, 1917, 1918 and 1919. The papers deal with problems of wound infections and their treatment, the growth of the bacillus of gas gangrene, acidemia in gas gangrene, acidosis of shock and suspended circulation, the physiology of wounds and related topics. The object of the volume presumably is to make more available for use in World War II information gained in World War I. The eminence of the author as a pioneer in the field of infectious disease makes the collected papers of particular interest to students of the problems of wound infections. Nevertheless the rapid development of sulfonamide therapy within the past few years and the newer modes of thinking about the therapy of infection make much of the discussion seem queer today. The terms "apo-phylaxis," "epi-phylaxis," "ec-phylaxis" and "kata-phylaxis" seem almost quaint now. The character of the war wounds of World War II has probably changed many of the modes of treatment as compared with World War I. It would be unwise, however, to forget some of the important lessons derived from the wounds of the first world war, and for that reason this volume should be in the hands of physicians and surgeons concerned directly with these problems. Sulfonamide therapy has not made obsolete the basic principles of immunology, and it will be unfortunate if overenthusiasm for chemotherapy should lead to the forgetting of lessons learned at great cost in the past. The volume is well printed, well bound and adequately illustrated. If for no other reason than a historical one its publication, in the opinion of the reviewer, is worth while.

An Introduction to Materia Medica and Pharmacology. By Hugh Alister McGugan, Ph.D. M.D. Professor of Materia Medica, Pharmacology and Therapeutics, University of Illinois College of Medicine, Chicago, and Elsie E. Krug, B.S. R.N. Science Instructor, St. Mary's School of Nursing, Rochester, Minn. Third edition. Cloth. Price \$3.50. Pp. 779 with 83 illustrations. St. Louis: C.V. Mosby Company, 1942.

Since McGugan rewrote the older Brodie textbook on materia medica in 1936, two more editions have been necessary. This attests the book's usefulness. The present edition is longer by 200 pages than the first, and to the reviewer, who has taught the subject for several years, this seems unfortunate. The book has become encyclopedic, which adds to its value as a work of reference but discourages the busy student nurse who wants, and should have, a concise, pertinent textbook. A single course involving both pharmacology and therapeutics, as in the usual materia medica for nurses, is difficult to present because of the two approaches necessary, that from drugs and that from diseases. McGugan and Krug consider the subject from the pharmacologic point of view, which is definitely the superior in a book of this type.

There are certain attitudes in the book which, it may be hoped, will be rectified in later editions. One is the use of proprietary names in certain places in the text without their official counterparts. Thus Cremalin, Atophan, Veronal, Nembutal and Pyramidon appear without qualification in some places and more correctly in parenthesis in other places. Of doubtful desirability for nurses, even in a source book, is the inclusion of such rare or archaic agents as cotarnine, coriandrum sativum (with a full page colored plate, of which there are too many of uncertain value for nurses), quillaja bark, serpentaria, kino,

krameria, black wash, creosote carbonate, sulfur tablets, ichthyol pills, rhus glabra, asafetida pills and althea (described both as "much used" and "rarely prescribed"). A lack of judicious selection is indicated by giving more space to the bromides than to the barbiturates, for giving detailed chemical formulas for the relative unimportant steps in the degradation of gallic acid to catechol and for giving in detail the method of intravenous injection, which is usually reserved for physicians. In certain places the colored plates appear to be without explanation in the text as with *Camellia thea*. The description of the "syndrome of crocodile tears" is misplaced in a book on materia medica for nurses. The printing is for the most part excellent, although the chart showing the action of caffeine is partly illegible and the picture of the cretin very dim. In most places American spelling is used, and it would have been preferable to express amoebiasis, bacteriocidal, Hindoo and leucemia in more ordinary form. It is disappointing that the revision could not include the changes of the current revisions of the U.S. Pharmacopeia and the National Formulary.

There are occasional therapeutic lapses from sound practice such as the mention of sulfanilamide given intravenously, the use of alcohol for chills from exposure and to break up a cold in shock, and as a poultice for erysipelas, and the recommendation of bromides as the physiologic antidotes for camphor, without reference to more potent sedatives. Colchicine does not appear in the index or under gout, no mention is made of dihydrotachysterol in the discussion of the parathyroids, mercurial diuretics are recommended in nephrosis, and mercury is stressed instead of bismuth in the treatment of syphilis (without mention of orally absorbable bismuth compounds). In the treatment of burns, blood and plasma transfusions are not mentioned and the recommendation of cardiac depressants when the heart is overstimulated or inflamed is at best loosely stated. The physiologic discussions are generally good, as are the pharmacologic sections. The relatively few questions at the end of the chapters are more proper and relevant than those in many text books, and the limitation of references is also commendable in a book for nurses. The volume is far more than the "introduction" suggested in its title, but it should be a satisfactory textbook for materia medica and a valuable reference book for later years.

Nasal Medication. A Practical Guide. By Noah D. Fabricant, M.D. M.S. Associate in Laryngology, Rhinology and Otolaryngology, University of Illinois College of Medicine, Chicago. Cloth. Price \$2.50. Pp. 197 with 20 illustrations. Baltimore: Williams & Wilkins Company, 1941.

The last forty years have seen great developments in rhinology. The first great advance followed the discovery of the medical uses of cocaine as a local astringent and anesthetic and the form of practice was determined by anatomists and surgeons. The pronounced surgical point of view that arose developed its own evils, and it required the physiologist to correct errors resulting from behavior predicated on the idea that operative procedures were the chief reliance for the cure of many diseases of the nose.

Knowledge of normal function and behavior of the lining membrane of the nose and its accessory sinuses received its main impetus in this country from the studies of Proetz, Hilding and others. Medications freely used up to this time were found harmful to ciliary action of the cells of the mucosa of the nose. Only preparations which had been widely favored were seen to carry the threat of lipid pulmonary changes. Walsh and others pointed out, furthermore, that immunologic changes could be obtained locally following instillation of certain bacterial preparations.

To Fabricant is due the acknowledgment of a carefully controlled physiologic study pointing out "the significance of the pH factor as a basis for the treatment of upper respiratory infection." This textbook begins with a well written introductory portion that is of anatomic, histologic and physiologic interest. The author then takes up the practical aspects of nasal medication founded on his own and those other physiologic and immunologic studies of the past ten or fifteen years which have so much altered the thinking and practice of rhinology.

Because the discussion is not academic, and because the material covered is of prime importance, this work is just the sort of textbook the practicing rhinologist should read and carefully follow.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HALOWAX ACNE

To the Editor—A man aged 26 who handles DeGaussing cables daily has a stubborn acneform condition which he and six of his co-workers attribute to some ingredient in this cable. Can you tell me what the ingredients are? Has Halowax, which these cables contain, been known to sensitize or poison any workers? His wife has some of the same lesions on the arms and face. How might one explain that? The man has had these acne-like lesions for six months, has had x-ray and other treatments with little good effect and now he has come to me. He has been away from his work for five weeks. The improvement has not been convincing. Could his liver be involved or damaged?

Adrian H. Scollen, M.D., Portland, Maine

ANSWER—Degaussing cables are used on ships. Each cable consists of a number of strands of copper wire coated with a white metal that may be zinc or tin or silver. Around the strands is wrapped Halowax, which consists essentially of trichloronaphthalene and chlorodiphenyl. This acts as an insulator and is water proof and fire proof. Around the Halowax cover is wrapped a transparent wrapping of cellophane. Around this is wrapped some rubberized fabric and this again is covered with woven rayon. Many of these individual cables are grouped together and covered with rubberized insulating material to form one large cable.

Halowax is impregnated into the rayon covering of the cable and is freely sprinkled between the individual cables comprising the large cable.

When these cables are spliced, especially if the splicing occurs in a closely confined space on board ship, the electricians are exposed to the solid granular form of Halowax and to the fumes of it as the cable splice is "boiled out" to seal.

Halowax acne among workers doing this work is common. It has occurred in practically every shipyard where the Degaussing cables are handled. Halowax acne is described by

Schwartz, Louis and Tulipan, Louis. *A Textbook of Occupational Diseases of the Skin*. Philadelphia, Lea & Febiger, 1939.

Drinker, C. K., Warren, M. F. and Bennett, G. A. "Certain Chlorinated Hydrocarbons." *J. Indust. Hyg. & Toxicol.* 19: 283 (Sept.) 1937.

Jones, Jack W. and Alden, Herbert S. "An Acneform Dermatitis." *Arch. Dermatol. & Syph.* 33: 1022 (June) 1936. "Skin Hazards in American Industry." *Pub. Health Bull.* 229, part II, pp. 7-12.

Morris, G. E. and Tabershaw, I. R. "Cable Rash"—A Note on a New Cleansing Mixture. *THE JOURNAL*, Jan. 16, 1943, p. 192.

Halowax does not sensitize workers. It causes an acneform eruption on the face, arms and other exposed parts of the body of every worker who is sufficiently exposed to it and does not take the recommended preventive measures.

Yellow atrophy of the liver has occurred among workers exposed to these substances.

It has been reported that the wives, children and others who handle or wash the Halowax-soiled clothes of workers have also developed such acneform lesions.

The treatment of these cases consists in preventing further exposure to the Halowax by placing exhaust ventilation over processes in such a manner as to draw the fumes away from the worker, by the use of protective ointments on the face, by the daily change to clean work clothes, and by daily compulsory supervised shower baths after work. The work clothes should be cleaned daily at the factory and not be taken home. The individual lesions are best treated by making a slight incision and expressing the contents. The patient should be given a strong cleansing solution for the face, such as "Tersus," made by Doak Company, Cleveland, or tincture of green soap, and advised to use it several times a day. At night he should use lotio alba. X-rays should be used cautiously if at all because the rationale for their use is not the same as in acne vulgaris.

Liver function tests are advised for the patient to see whether he has suffered any liver damage.

ELEVATED ST SEGMENT OF ELECTROCARDIOGRAM

To the Editor—What is the significance of a slight elevation of the ST segment in leads 2 and 3 with no other electrocardiographic finding?

M. D., Wisconsin

ANSWER—A slight elevation of the ST segment in leads 2 and 3 without other electrocardiographic findings is not of dependable diagnostic significance.

DIAGNOSIS OF SUDDEN COLLAPSE

To the Editor—A white man aged 39 apparently in good health with a normal previous history was suddenly seized with an attack of severe precordial pain radiating to the left arm, dyspnea, cyanosis and collapse which occurred while he was sitting and observing hunting field trials. His blood pressure was not obtainable. He was attended by a nearby physician and sent home after rallying from this attack. On arising one day after having been in bed two weeks, he felt a severe pain in the right upper quadrant of his abdomen which was followed by nausea and vomiting for two days. This subsided with restriction of diet and bed rest. Dyspnea on exertion in bed continued and an upright position was necessary. An electrocardiogram was normal. He was hospitalized for observation at this time and the usual blood examination (complete blood count and Wassermann test) was normal as was the urinalysis. An electrocardiogram was negative for myocardial damage or coronary artery disease at this time. The blood pressure was 122 systolic, 62 diastolic. One week later a precordial pain suddenly developed, which was relieved by morphine. Subsequently a headache and paralysis of the left side of his face and left arm with a weakness of muscular action of his left leg developed. The blood pressure in the left arm was 110/62 and in the right arm 122/70. Following this he slowly regained use of his left arm. During the ensuing three weeks period there appeared occasional petechiae involving the fingers of his left hand. Dyspnea still persisted on moderate exertion in bed. Repeated blood count, urinalysis and blood chemistry were normal. During his stay in the hospital examination of the heart did not show enlargement or murmurs and the force of contraction appeared only slightly impaired. A third electrocardiogram was made about five weeks after the initial attack and again failed to show any deviation from normal. The paralysis on the left side gradually cleared up and after six weeks stay in the hospital he was sent home. Slight dyspnea on exertion still persisted after discharge from the hospital. The general physical examination now is essentially normal except for a slight residual weakness of the left arm and the blood pressure in the left arm is 110/60 as compared with 124/80 in the right arm. All electrocardiograms were interpreted by a qualified cardiologist. Is it possible that this patient had had coronary artery disease in spite of three successive normal electrocardiograms? Could abdominal symptoms, petechiae and paralysis on the left side be explained on any other basis than that of embolic phenomena, for example a local vascular disturbance?

M. D., New Jersey

ANSWER—One is not justified in diagnosing serious heart disease with myocardial failure in the presence of a normal physical examination of the thorax and repeatedly normal electrocardiograms, especially if one assumes the heart to be absolutely normal in size, in such a case as that noted here. It is a safe rule that dyspnea is not to be ascribed to failure of a heart that is normal in size. Also it is extremely rare to have systemic arterial embolism, which would include cerebral embolism unless there is more evidence than has been given in this case either of myocardial infarction with intracardiac thrombosis, subacute bacterial endocarditis almost always implanted on obvious valvular disease or congenital heart defects, definite mitral stenosis with left auricular enlargement, or arrhythmia such as auricular fibrillation in which auricular thrombosis may occur. It is indeed difficult on the findings as presented to link together under one heading the various symptoms in this case, namely the severe precordial pain with collapse at the onset, the severe pain in the right upper quadrant of the abdomen with nausea and vomiting for two days, the dyspnea on slight exertion afterward, the recurrent precordial pain and the paralysis on the left side. On the other hand, the blood pressure difference in the two arms and the petechiae involving the fingers of the left hand are not important and are probably simply related to disturbance of the circulation in the left arm secondary to the hemiplegia.

If one could feel doubtful about the normality of the physical examination of the heart and the electrocardiogram, then a diagnosis of myocardial infarction followed by dilatation and failure of the left ventricle and cerebral embolism secondary to intracardiac thrombosis would be in order. That, even on the face of the case report as given, is the best bet. Other rarer conditions, such as dissecting aortic aneurysm and extensive peripheral vascular disease, including periarteritis nodosa, are much less likely.

INTRANASAL VACCINATION AGAINST COLDS

To the Editor—Recently I was requested to purchase from the Cutter Laboratories a substance called N.V. Nasal, a bacterial vaccine supposedly good to prevent colds and respiratory infections by the nasal spray method. Could you give me any information as to the value of this type of medication?

M. D., Idaho

ANSWER—The use of bacterial vaccines by the intranasal spray method is based on experimental evidence (Cannon and Walsh) that by this method a greater concentration of immune bodies is found in the nasal mucosa than in other organs and tissues of the body, and in some instances a concentration equal to that found in the blood serum. In other words it appeared that the immune bodies might be produced locally in the mucosa and remain there in greater concentration. On the theory, therefore, that greater protection might be afforded if immune bodies could be accumulated at the point of entry of the infection,

the intranasal method of vaccine therapy in human beings was started

Clinical experience is not sufficiently conclusive to endorse this form of prophylaxis. In general, cold vaccines, no matter what the route of administration, have not come up to expectations. There have not been any forms of cold vaccines which have been accepted by the Council on Pharmacy and Chemistry. Present day medical opinion supports the view that no substance or mixture of substances can be relied on to prevent or cure colds.

COCAINE AS LOCAL ANESTHETIC

To the Editor—Dr Stapleton states in a communication to *The Journal* (Oct 24 1942 p 642) that 2. When used locally either topically or injected it [cocaine] should be combined with epinephrine to prevent absorption. Is it safe to inject cocaine under any conditions? I was taught that cocaine injected would always result in severe cocaine poisoning. Has something new been added that cocaine can now be used parenterally?

Michael A Ferrara, M.D. Norwich Conn

ANSWER—It is possible that the inquirer has misinterpreted what he was taught. Cocaine, of course, was the first local anesthetic agent and was used some sixty years ago. The original work on the effects of local agents when injected was all done with cocaine. The classic contributions of Halsted illustrate this fact. When procaine hydrochloride was introduced during the early years of this century it proved to be much less toxic than cocaine when injected, and the injection of cocaine therefore became less common. However, in one large clinic many thousand tonsillectomies were performed with one fifth of 1 per cent cocaine as the sole anesthetic agent used. Injections were done deliberately with an extremely small syringe and excellent results were obtained. A teacher of pharmacology might say that cocaine when injected after the fashion ordinarily employed for procaine hydrochloride, would result in a high percentage of severe reactions and that such use of cocaine was not advisable.

The addition of epinephrine to local anesthetic solutions adds an advantage and a disadvantage. Epinephrine itself is a toxic agent and some patients are hypersensitive to its effect just as some patients are hypersensitive to the effects of local anesthetic agents. It has the advantage, however, of constricting the capillary bed in the region injected or in the mucous membrane where topically applied, thus reducing the rate and possibly the amount of absorption. Since toxicity depends on several factors (including the rate of absorption) epinephrine may be of value. It is generally understood that the upper limit of concentration of epinephrine in anesthetic solutions should be 5 minims of 1 to 1,000 solution in 100 cc. of anesthetic solution to be injected. Higher concentrations of epinephrine have been found to be unnecessary and often dangerous. Whether much higher concentrations of epinephrine are permissible with anesthetic agents to be topically applied is an unsettled question.

The answer to the question "Has something new been added?" is definitely "No." To the question "Is it safe under any condition to inject cocaine?" the answer is probably "Relatively safe." The best safeguard is the application of meticulous care and deliberation in the administration of local anesthetic drugs with due consideration for the pharmacologic characteristics of the drug used.

RADIUM EMANATION OR X RAYS FOR HYPERTROPHIC TONSILS IN PURPURIC PATIENT

To the Editor—Can a local application of a radium plaque filtered or unfiltered, help tonsillar hypertrophy? The sufferer in question has thrombocytopenic purpura and for that reason the tonsils though tremendously big cannot be removed.

M.D., Massachusetts

ANSWER—Radium emanation, if it could be used in the amounts and after the method employed by the staff at Johns Hopkins Hospital, might be useful in a case such as that described. If emanation is not available, then either roentgen therapy or radium would be the next method of choice. It is not practicable to use a plaque with a small amount of radium. It would be difficult to keep the plaque in place long enough for satisfactory results.

HIGH RED CELL COUNT AND HEMOGLOBIN

To the Editor—A plethoric extremely muscular white man aged 28 whose nude weight is 199 pounds (90 Kg.) height 5 feet 5½ inches (165 cm.) standard weight 143 pounds (65 Kg.) complains of pain in his right heel. The onset of the pain was in November 1940 while he was operating a sewing machine. X-ray examinations revealed roughening of the os calcanei, suggesting a bursitis. However, the question of thrombosis of an artery resulting from polycythemia came up. The following blood studies were obtained Aug 25 1942: red blood cells 6,230,000, hemoglobin 16.2 Gm, white blood cells 10,650. Schilling differential: stab cells 5 per cent, segmented cells 57 per cent, lymphocytes 26 per cent, mononuclears 9 per cent, eosinophils 2 per cent, basophils 1 per cent. The smear revealed no normoblasts. The platelet count was 405,000 and hematocrit 49 volumes per cent. September 22 1942: red blood cells 6,980,000, hemoglobin 17.2 Gm, white blood cells 11,000. Schilling differential: stab cells 6 per cent, segmented cells 44 per cent, lymphocytes 38 per cent, mononuclears 8 per cent, eosinophils 3 per cent, basophils 1 per cent. The smear revealed no normoblasts. The platelet count was 450,000, hematocrit 46 volumes per cent. At no time has the spleen been felt. The patient has a natural ruddy color, is unusually well built and appears to be healthy. The essentially normal platelet count, the normal smear and the essentially normal hematocrit seem opposed to a diagnosis of polycythemia.

Charles L. Steinberg MD, Rochester N.Y.

ANSWER—The first blood count is within normal limits for a young adult man (Wintrobe M.M. *Bull Johns Hopkins Hosp* 53 118 [Sept] 1933). As the second hematocrit was somewhat lower than the first it would appear that the higher red count and hemoglobin value were due to an error in technique. Errors in red cell counting and hemoglobin determinations are common. There is not sufficient evidence for a diagnosis of polycythemia in this case.

COLOR VISION TEST CHARTS

To the Editor—In view of the government's calling for use of the Ishihara color blindness test charts and the report by local surgical supply houses that they are not obtainable in the United States as they were made in Japan and the supply in this country is exhausted I cannot but ask whether manufacture in the United States is precluded by some patent right that has not as yet been taken over from the enemy or whether our technicians have not yet learned how to print them. I can hardly believe that we are technically unable to reproduce them and the fact that *Life* magazine back in 1939 printed some of the charts in the magazine would seem to show that they can be made here. These charts seem to be a necessity and I can think of few matters in which *The Journal* can better exert itself than in assuring that the profession have access to an adequate supply of them and at a reasonable price—not the \$7.50 original price or the \$15 which was asked for the last one I heard of for sale. They are called for not only for use of the eye specialists but by every general practitioner who examines a truck driver for a civilian employee's job.

E. M. Wilder M.D. Sacramento Calif

ANSWER—The American Optical Company has published and has on sale, at approximately \$10 retail, a Pseudo-Isochromatic Color Test which was designed for use by the Army and Navy. This contains a set of colored plates similar to the ones found in the Ishihara and the Stilling color tests and atlases and is quite adequate for use in testing for color blindness.

GLASS CARTRIDGES FOR ANESTHETIC SOLUTIONS

To the Editor—Kindly let me know whether there are any objections against using 1 per cent or 2 per cent procaine hydrochloride epinephrine solutions filled in glass cartridges which have a rubber plunger on one side and a rubber cap on the other side. Does any possibility exist of contamination when puncturing the rubber cap with the injection needle? If there is any literature on this subject I should appreciate it if you would give references.

E. Markay Pullen M.D. New York

ANSWER—There are certain physical peculiarities in the behavior of a cartridge in a cartridge syringe. For instance, owing to the elasticity of the rubber plunger there may be a tendency for the cartridge to 'suck back' when pressure is released. Of course there are certain advantages, such as speed and convenience.

The possibility of contamination when puncturing the rubber cap does exist and it is therefore desirable to disinfect the surface of the rubber cap as well as possible before use. Seventy per cent alcohol has been employed for this purpose. A soft metal protective cap is used on one brand of cartridge. This cap can be flamed gently. The advisability of dispensing solutions in this manner is debatable.

TREATMENT OF UNDESCENDED TESTIS IN INFANCY NOT ADVISED

To the Editor—Please advise the earliest age to begin gonadotropin injections for an undescended testis in a baby now 10 weeks old.

M.D. New York

ANSWER—The baby is entirely too young to start treatment. If the testis has not descended by the time the boy is 3 or 4 years old the method of treatment can be decided on at that time.

LIFE AFTER NEPHRECTOMY

HERMAN L KRETSCHMER, MD

CHICAGO

Whenever told that removal of one kidney is indicated, a patient always, or nearly always, asks three questions 1 Can I live with only one kidney? 2 Will it shorten my life? 3 Will the removal of one kidney handicap me and limit my work and activities?

It is extremely interesting to note the great regularity with which these questions are asked and, in most instances, they are asked before the question of operative mortality is discussed. It almost seems to be intuitive.

To the first question one answers "yes" without hesitation and cites many instances illustrative of the fact that patients live for a long time after a nephrectomy, and one further fortifies the remark with the statement that some patients are born with only one kidney and live to a ripe old age only to die of some intercurrent disease or some accident. In response to the second question one answers "no." In reply to the third question one answers in the affirmative by stating that certain precautions must be taken.

However, if the patient asks one to present evidence in support of these statements, then one finds oneself in a position of embarrassment as the result of a lack of information on these points. In order to be able to answer the question How about life after nephrectomy? based on evidence I thought it might be interesting and desirable to study in detail a series of patients on whom nephrectomy had been performed.

This paper is based on a study of 156 patients. They were asked to report in person at the Presbyterian Hospital, where the examinations were carried out. Neither technical details of the operation nor operative mortality and morbidity will be dealt with here. The number of cases does not represent all the patients on whom I have performed nephrectomy but represents only those patients who, in response to my request for study and examination, presented themselves at the hospital. It was my opinion that this was the only accurate method so far as evaluation is concerned, since a study based on answers to a questionnaire would be open to doubt.

In this study the following data were recorded: intervals that elapsed between nephrectomy and examination, presence or absence of urinary symptoms as well as general symptoms, question of whether or not the patient had pain in the remaining kidney, results of the physical examination, changes in weight since

the operation, blood pressure before operation and on examination, analysis of the urine, including chemical examination and culture, nonprotein nitrogen of the blood, results of the Newburgh test, results of examination of the genitourinary tract with roentgen rays and intravenous pyelograms.

In table 1 is given a list of the various lesions for which nephrectomy was performed.

NEPHRECTOMY FOR TUBERCULOSIS

Forty-nine patients on whom I performed nephrectomy for renal tuberculosis presented themselves for examination. The youngest patient was 10 years of age, the oldest 75, the average age was 44 years and 6 months. The longest period between the operation and examination was twenty-four years and eleven months, the shortest one year and four months, the average time was ten years and three months.

Urinary Symptoms—Fifteen patients had some burning and frequency of urination. An analysis of these cases disclosed that the symptoms in 2 cases were due to benign prostatic hypertrophy. An analysis of the remaining 13 cases is given in table 2.

Two patients had an attack of acute pyelitis, one four years, the other six years after nephrectomy, and 1 patient passed a stone.

Pain in the Remaining Kidney—There was only one instance in this group in which the patient subsequently developed pain in the remaining kidney.

Physical Examination—The results of the physical examination are given in table 4.

Weight—In 4 cases there has been some loss of weight. The largest gain was 62 pounds (28 Kg.).

Blood Pressure Studies—In only 7 cases were changes in the blood pressure noted. In 4 there was an increase and in 3 a decrease, as presented in table 5.

Urinalysis—Albumin was present in 6 cases and pus in 13 cases. Tubercle bacilli were found in smears or in guinea pigs or both in 10 cases.

Cultures—Positive cultures were obtained in 14 cases (table 6).

Blood Chemistry—In 10 cases there were no records of preoperative studies of the nonprotein nitrogen. Of the remaining 39 cases the studies disclosed that the nonprotein nitrogen values were increased in 9 cases. In only 3 cases were the values above 50 mg per hundred cubic centimeters of blood, as recorded in table 7.

Newburgh Test—The test was performed on 35 of the 49 patients. Of the 35, 24 passed and 11 did not, a percentage of 69 disclosing normal function.

Roentgen Examination—In 11 cases the intravenous urograms revealed definite changes from the normal,

such as dilatation of the pelvis, clubbing of the calices with irregularity, and dilatation of the ureter. In 5 of these 11 cases a proved tuberculosis of the remaining kidney was present.

Scoliosis was present in only 3 cases.

11	♀	44	Tuberculosis of bladder and kidney, bilateral	
12	♀	53	Tuberculosis of bladder and kidney	
13	♀	44	Tuberculosis of bladder and kidney	

TABLE 3—General Symptoms

	Patients
Edema of ankles	4
Dyspnea	4
Headache	2
Constipation	2
Spastic bowel	1
Fatigue	1

NEPHRECTOMY FOR CALCULI

Forty-two patients who had nephrectomy for stone presented themselves for examination. The oldest patient was 76, the youngest 19, the average age was 51. The longest period between the operation and the examination was twenty-one years, the shortest period one year and one month, the average period was seven years and nine months.

Pain in the Remaining Kidney—There were 4 patients in this group who subsequently developed pain in the remaining kidney. The pain suffered by 2 of these patients was due to the presence of stones and of 1 to recurring attacks of pyelonephritis, no reason for the pain of 1 was found other than enlargement of the kidney outline as shown in roentgenograms.

Weight—The weight either remained the same as it was prior to operation or it increased. Three patients gained 50 pounds (22.7 Kg.).

Blood Pressure Studies—Seven patients showed changes in the blood pressure readings. Four showed an increase and 3 a reduction, the blood pressure of 1 prior to operation was not recorded, although twenty years later it was abnormally high, as listed in table 10.

Urinalysis—Albumin was present in 6 patients (in 2 due to stones in the kidney), and pus was present in 11. Positive cultures were obtained in the urine of 15 patients, as shown in table 11.

An analysis of the group in which urinary conditions were noted discloses that the cause of the positive findings in the urine of 6 patients (33 1/3 per cent) is quite independent of nephrectomy, since in 3 the findings are due to benign prostatic obstruction and in the other 3 to chronic prostatitis. In 3 the changes are due to stones in the remaining kidney. In 3 there are present definite hypertension and cardiac enlargement. In 6 cultures were positive. One patient has had several attacks of pyelitis. The remaining 5 have no symptoms and were unaware of the fact that their urines were positive on culture. Of the entire group of 42 patients, positive cultures were obtained in 15.

Blood Chemistry—There was an increase in the non-protein nitrogen values in the blood in 14 cases. In only 3 cases were the readings over 50 mg. per hundred cubic centimeters of blood, and in 11 cases the readings were between 40 and 50 mg. per hundred cubic centimeters of blood.

Newburgh Test—The test was made on 38 of the 42 patients. Of these 38, 25 passed and 13 did not, 66 per cent passing.

Roentgen Examination—Plain films and intravenous urograms revealed that 11 patients had enlargement of the kidney shadow, 3 patients scoliosis, 6 patients enlargement of the kidney pelvis and 3 patients dilatation of the ureter.

NEPHRECTOMY FOR HYDRONEPHROSIS

There were 40 patients studied in the hydronephrosis group. The youngest was 3 years, the oldest 77 years of age. The average age was 35 years and 6 months.

TABLE 4—Results of Physical Examination

Sex	Age	Positive Findings	Time Since Operation		Comment
			Yr.	Mo.

Sex	Age	Before Operation, Mg per 100 Cc	After Operation, Mg per 100 Cc	Diagnosis
♂	42	27	50	Tuberculosis of other kidney
♂	49	28	56	Tuberculosis of bladder
♂	44	30	70	Tuberculosis of other kidney

TABLE 8—Urinary Conditions Presented by Patients With Calculi

Sex	Age	Positive Findings	Time Since Operation
♂	73	Benign prostatic obstruction	1 year 8 months
♂	76	Benign prostatic obstruction	13 years 3 months
♂	57	Recurrent pyelitis stone in kidney	4 years 6 months
♂	58	Pyelitis stone in kidney	5 years 2 months
♂	34	Pyelitis stone in kidney	9 years 8 months
♂	54	Recurrent pyelitis	5 years 3 months
♂	50	Impacted stone in ureter	20 years
♂	51	Nocturia (1 x)	12 years 10 months
♂	28	Nocturia	4 years 9 months

Pain in Remaining Kidney—Only 2 patients complained of pain in the remaining kidney

Physical Examination—The data given in table 13 were obtained on physical examination

Weight—All patients have held their previous weight or gained weight, in several instances as much as 50 pounds

Blood Pressure Studies—Increase in blood pressure was noted in only 3 cases, as recorded in table 14. In 1 case (male) the blood pressure decreased from 160/115 before operation to 125/75 three years and eight months after operation

Urinalysis—In only 4 cases was the presence of albumin disclosed, a few pus cells were disclosed in 8, casts in none. In 17 cases the urine was sterile, in 2 no cultures were obtained, in 11 growth on culture was obtained as shown in table 15

Blood Chemistry—In only 4 cases was there an increase in the nonprotein nitrogen values in the blood. Values of 44, 41, 95 and 44 mg per hundred cubic centimeters of blood were recorded. In 13 the nonprotein nitrogen before operation was not recorded

Newburgh Test—The test was performed on 31 of the 40 patients. Of the 31, 22 passed and 9 were unfavorable, a percentage of 70 disclosing normal function

Roentgen Examination—Examination disclosed the presence of scoliosis in 6 cases. Flat film disclosed an enlargement of the kidney outline in 4 cases (compensatory hypertrophy). The intravenous pyelograms disclosed a slight enlargement of the pelvis in 7 cases

In 3 the question was raised as to whether or not the enlargement was due to hypertrophy (functional following overwork of one kidney). In 1 case there was definite hydronephrosis, and in 1 there was clubbing of one calyx. In several cases old films for purposes of comparison were not available

NEPHRECTOMY FOR TUMOR

Eleven patients on whom nephrectomy was performed for malignant tumor reported for examination. The youngest patient was 14 years of age, who at the time of operation was 1 year and 2 months old. The oldest patient was 72 years of age. The average age was 50 years. The longest period that elapsed between operation and examination was twelve years and ten months, the shortest one year and one month and the average time was five years and eight months

Symptoms—Urinary symptoms were lacking, general symptoms too were lacking, except for 1 patient who had indefinite pains in the right upper quadrant (possible recurrence?)

Pain in Remaining Kidney—None of the patients complained of pain in the remaining kidney

Physical Examination—Examination was negative in all cases

Weight—There was no loss of weight in this group of patients, either they have the same weight they had at the time of operation or they have gained. The largest weight gain was 40 pounds (18 Kg.)

TABLE 9—General Conditions Presented by Patients With Calculi

Sex	Age	Positive Findings	Time Since Operation
♀	57	Cardiac enlargement hypertension	4 years 5 months
♂	71	Cardiac enlargement (present at time of operation)	1 year 8 months
♀	68	Cardiac decompensation	1 year 3 months
♂	72	Anginal attacks?	6 years 10 months
♂	76	Mild angina	13 years 3 months
♂	40	Hypertension (present before operation)	1 year 7 months
♀	41	Cholelithiasis	5 years 8 months
♀	44	Cholelithiasis	3 years 3 months
♂	51	Cholelithiasis	1 year 1 month
♂	61	Peptic ulcer	6 years 1 month

TABLE 10—Blood Pressure

Age	Sex	Preoperative	Postoperative	Time Since Operation

Diplococci	1

Blood Pressure—There were no changes in the blood pressure except in 1 case in which the blood pressure was 125/80 before operation and at present is 176/110 seven years after nephrectomy. The patient is now 62 years of age and has cardiac enlargement

Urimalysis—Examination of the urine revealed the presence of albumin in only 2 cases and the cultures in all were sterile

Blood Chemistry—In 5 cases there was an increase in the nonprotein nitrogen—namely, 44, 46, 51, 56, 59 mg per hundred cubic centimeters of blood. In

TABLE 12—General Symptoms

Sex	Age	Symptom	Flapae of Time Since Operation

♂	62	Cardiac enlargement moderate	3 years 2 months
♀	40	Enlarged thyroid	15 years 8 months
♀	30	Systolic murmur	2 years 8 months

other words, there was a beginning impairment of kidney function in 5 of the 11 cases, or in 45.4 per cent.

Newburgh Test—The test was performed on 10 patients and not on 1. Of the 10, 9 passed and 1 failed, a percentage of 90 passing.

Röntgen Examination—In 1 case a slight hydronephrosis and a slight scoliosis exist. In 1 case two small stones which were present in the opposite kidney before operation have increased slightly in size since nephrectomy, six years and seven months ago.

NEPHRECTOMY FOR MISCELLANEOUS LESIONS

In table 16 is given a list of the various lesions for which nephrectomy was performed.

The youngest patient was 31 years of age, the oldest 73, the average age was 52 years. The longest period between operation and examination was twenty years, the shortest two years, the average time was nine years and six months.

TABLE 14—Incidence in Blood Pressure

Symptoms—Two women, aged 70 and 73, have had an occasional attack of frequency of urination. One patient has right upper quadrant pain due to cholelithiasis.

Pain in Remaining Kidney—There were no instances of pain in the remaining kidney.

Physical Examination—Examination was negative for all patients except 2. 1 patient had an increase in

the blood pressure from 142/68 before operation to 195/85 five years after operation. The patient is 70 years old and has a systolic murmur, hypertrophy of the left ventricle and extrasystoles. One patient has an enlarged thyroid.

One patient had a decrease in blood pressure from 170/84 to 134/80 six years and nine months after operation.

Weight—Four patients have had an increase in weight, 9 have shown no change and 1 patient showed a loss of 4 pounds (1.8 Kg).

Urimalysis—Examination of the urine revealed the presence of leukocytes in 3 cases. Cultures were sterile in all but 4 cases, in which organisms were obtained as shown in table 17.

Blood Chemistry—The nonprotein nitrogen studies in all cases were normal before operation, the nonprotein nitrogen was increased in only 1 case.

Newburgh Test—In this group of 14 patients the test was made on 12, all of whom passed, giving 100 per cent.

Röntgen Examination—Studies revealed 1 case in which the kidney outline was enlarged and 1 in which there was a slight scoliosis. Intravenous pyelograms disclosed that in only 1 case was a slight enlargement of the pelvis evident (hypertrophy?).

CARDIAC INVOLVEMENT

In answer to the question "What about cardiac function after nephrectomy?" this study discloses that cardiac enlargements, murmurs, attacks of angina and extrasystoles occurred as follows: in tuberculosis, 12.24 per cent, stone, 11.9 per cent, hydronephrosis 17.5 per cent, and in the miscellaneous group, 7.1 per cent. An analysis of the group discloses that 3 of the 7 patients with tuberculosis were over 50 years of age. Of the 5 patients with stone who had cardiac changes 1 was 52 and the other 4 patients ranged from 62 to 76 years. In the hydronephrotic group 5 of the 7 patients were over 60. In the miscellaneous group the 1 cardiac patient was over 70.

HYPERTENSION

What about the blood pressure after nephrectomy? What can we tell our patient will happen to his pressure after nephrectomy?

In the tuberculous group there was an increase in blood pressure in 4 cases and a decrease in 3. In other words, the patient has a 12.25 per cent chance of an increase in his blood pressure. In 1 case there was a reduction in the pressure from 280/100 to 175/70, which is still up.

In the stone group there was an increase in 5 cases, or 11.9 per cent, and a decrease in 3, or 7.1 per cent.

In the hydronephrosis group there was an increase in 3 cases, or 7.5 per cent.

In the tumor group there was only 1 case that showed an increase, or 9 per cent

In the miscellaneous group there was an increase in only 1 case, or 7.1 per cent

NEWBURGH TEST

Of the 156 patients who returned for examination the Newburgh test was done on 126, of which number 92, or 73 per cent, passed. The patients are thus divided sharply into two groups: the smaller groups, composed of 12 miscellaneous and 10 tumors, in which all but 1 passed, whereas in the larger groups of hydronephrosis, tuberculosis and stones there was a very definite and constant percentage running between 66 and 70, and critical analysis of all the data available discloses no reason for this sharp and apparent definite difference. When these groups are correlated with elevation of blood pressure, retention of nonprotein nitrogen or other factors there are no constant deviations which would indicate any of them as a source of the difference. It is true that scattered throughout these groups there are occasional hypertensives and some increased nonprotein nitrogen, but these cases are so evenly distributed that they are definitely not statistically significant. It is possible that further search will reveal some factor which is more constant in determining this distinct difference while, on the other hand, it may be a matter of chance.

The conclusions reached in this study are that 73 per cent of those patients with only one kidney are able

TABLE 17—*Growth on Culture*

Hemolytic <i>Streptococcus viridans</i>	1
Hemolytic streptococcus	1
Colon bacilli	1
<i>Staphylococcus aureus</i>	1

to pass a test as rigid as that of the Newburgh concentration test, which is by far more drastic than many of the other tests popularly used, and that in certain series practically 100 per cent are able to pass the requirements of this test with one kidney only.

SCOLIOSIS

During this study I was impressed by the frequency with which Dr. Squire, head of the x-ray department of Presbyterian Hospital, reported the presence of scoliosis. This led to a review of the preoperative films. The films were also reviewed by Dr. Kellogg Speed.

Scoliosis was present in 18 of the 156 patients and was present on the side opposite the nephrectomy. A comparison of the present films disclosed that scoliosis was absent in 3 cases before operation and developed since operation.

Comparison of the films is summarized in table 18.

The occurrence of scoliosis in the various lesions for which nephrectomy was performed is given in table 19.

SUMMARY

From a review of the data obtained in this study the following statements are justified:

1 The average length of time that elapsed between the nephrectomy and examinations was eight years and two months. The longest period since the nephrectomy in this series was twenty-four years and eleven months.

2 The oldest patient at the time of nephrectomy was 72, one year and eight months having elapsed since the operation. The oldest patient studied in this series

is 77, a period of sixteen years having elapsed since the operation. The youngest patient at the time of nephrectomy was 10 months of age, a period of four years and six months having elapsed since the operation.

3 Pain in the remaining kidney does not occur with any great regularity, although the impression seems to prevail that this phenomenon is common following nephrectomy. It occurred in only 7 cases in this series.

TABLE 18—*Comparison of Films*

	Patients
Complete correction since nephrectomy	1
Almost complete correction since nephrectomy	1
Less scoliosis since nephrectomy	1
No change in scoliosis	7
Increase in scoliosis	3
Not present before operation	2
No preoperative films available	2

In some of the cases in which it occurred a pathologic condition in the remaining kidney, disclosed by study, was responsible for its presence. In short if the patient complains of pain in the remaining kidney one should not automatically assume that the pain is due to compensatory hypertrophy when in reality it may be due to organic disease.

4 There were 18 patients (11.5 per cent) who had cardiac involvement, 4 of whom were under 50 years of age. One patient had the cardiac hypertrophy before operation. The incidence of cardiac enlargement in a group of patients over 50 with nephrectomy is therefore about what one can expect in a similar age group with no nephrectomy.

5 In the largest number of cases the weight remained the same or there was an increase. In only 5 was there a loss. A gain of as much as 50 pounds was noted in 7 cases.

6 In 14 cases there was an increase in the blood pressure. Eliminating patients in whom hypertension was present before operation, the study discloses that the patients are well along in years, having reached a time in life when hypertension might be expected. There were only 2 patients with hypertension who were under 50 years of age. In 6 cases there was a reduction in the blood pressure but the amount of the reduction was not pronounced or very precipitate.

TABLE 19—*Scoliosis Among Nephrectomized Patients*

	Patients
Stone and scoliosis	8
Hydronephrosis and scoliosis	5
Tuberculosis	3
Tumor	1
True supernumerary kidney	1
Total	18

7 The results of the urinalysis depend on the lesion for which the nephrectomy was performed. In the 49 cases of renal tuberculosis pus was present in 14 and albumin in 6. In the 42 cases of stone, pus was present in 11 and albumin in 6, whereas in the remaining groups of 65 cases pus was present in 11 and albumin in 6. The cultures were more frequently positive in the group in which nephrectomy had been performed for stone. All cultures in the tumor group were sterile, four were positive in the miscellaneous group, eleven were positive in the group for hydronephrosis, fourteen were positive in the group for tuberculosis.

8 Nonprotein nitrogen studies were made in 146 of the 156 cases. The nonprotein nitrogen value was increased in 36, or 24.65 per cent. Of these 36 cases the nonprotein nitrogen value was normal before nephrectomy in 22, no preoperative studies were made in 8, and the nonprotein nitrogen was elevated before operation in 6 and remained so. So that, excluding the cases in which preoperative determinations were not made, elevation of nonprotein nitrogen occurred in 15 per cent.

9 Seventy-three per cent of those patients with only one kidney are able to pass the Newburgh concentration test.

10 Scoliosis was present in 18 of the 156 patients.
122 South Michigan Avenue

ABSTRACT OF DISCUSSION

DR MONROE E. GREENBERGER, New York. Dr Kretschmer has confirmed statistically the impressions that many of us have gained through clinical observation. Recently Addison has cast a doubt on the opinion held for many years that only a portion of the glomeruli are open at any one time. The newer physiologic observations signify that all functioning renal nephrons carry their loads simultaneously and that when some are removed the others must increase their load. Two additional complications presented by these tuberculous patients are amyloidosis and post-nephrectomy sinuses. In routine follow ups using the simple congo red test as modified at Ser View Hospital we find a high incidence of amyloidosis. For diagnosis we require 90-100 per cent absorption of the dye. This is found relatively often after nephrectomy for tuberculosis occasionally pyonephrosis, rarely cancer. There is usually an associated amyloid nephrosis. It is a frequent cause of albuminuria in these patients. The commonest postnephrectomy occurrence of amyloidosis is in cases with persistent tuberculous sinuses. Because of the amyloid nephrosis involving the single remaining kidney and the resulting uremia we believe in active, rapid treatment of tuberculous sinuses. An occasional patient may get along well. If these sinuses are not cleared up rapidly, amyloidosis will develop with resulting uremia. We try various methods of irrigation and if the sinus is not closed within six to eight weeks we advocate radical surgical removal of the sinus.

DR STANLEY R. WOODRUFF, Jersey City, N. J. Dr Kretschmer's study does not entirely answer the three questions cited at the beginning of the paper. Accompanying his study of the living patients should also go a historical review of those who have died, and for what reason. With these data at hand one would be better fortified to answer more intelligently the question whether a patient can live with one kidney. The answer is yes, and he can also die from uremia shortly after nephrectomy. Naturally those conditions in which there has been a gradual upbuild of compensatory function, as hydronephrosis, tumor and calculous pyonephrosis, will show the best postoperative results. One would expect to find in the 49 patients operated on for tuberculosis of the kidney that urinary symptoms and actual evidence of the disease was noted in the bladder or the remaining kidney. Patients should be taught that nephrectomy is more often a conservative operation than a radical one and that only in certain instances will it be necessary to inhibit activities in postoperative living. Dr Kretschmer's study certainly supports this statement. Tuberculosis heads the various conditions requiring nephrectomy in the need of postoperative care, and we can only hope for the time to come when patients with this condition will be given proper subsequent treatment. Patients who have been nephrectomized for calculous disease should be studied for a possible cause, nearly all other patients show conditions in which postoperative care means little.

DR HERMAN L. KRETSCHEMER, Chicago. In this series there were 47 patients who were operated on for renal tuberculosis. Seven of these patients are still having symptoms due to tuberculosis of the bladder and the removed kidney. In some of them the symptoms are due to contracted bladders, the result of the renal tuberculosis. I wish to agree with Dr Woodruff as regards the importance of postoperative care in the management of the patient on whom one has performed a nephrectomy.

THE REPAIR OF CRANIAL DEFECTS WITH TANTALUM

AN EXPERIMENTAL STUDY

LIEUTENANT (J. G.) ROBERT H. PUDENZ
MEDICAL CORPS U. S. NAVAL RESERVE

The surgeon planning repair of a cranial defect has a large number of methods from which to choose. At the present time the most favored techniques are those which employ autogenous tissues particularly bone and cartilage. However, the use of substances alien to the host has continued despite the popular aversion to the production of a foreign body reaction. Furthermore, enthusiasm for the alloplastic materials has recently been revived by the encouraging reports of Geib,¹ Beck² and Peyton and Hall³ on the repair of cranial defects with tantalum. In this paper certain observations on the experimental and clinical use of tantalum for this purpose are reported.

Before I discuss the alloplastic methods it is well to consider the advantages and disadvantages attending the use of autografts. Bone is obtained either from the adjacent skull with the Muller-Kong technique or one of its modifications or from the ribs, tibia, ilium or scapula. The principal advantage of these techniques is that the living tissue of the host is used, thus obviating reaction to a foreign body. The objections to the use of autogenous bone are that either a more extensive procedure or a second operation is required and that absorption of the grafts may occur. Ney⁴ has reported 44 cases of cranioplasty with autogenous bone from World War I in 34 of which there was either partial or complete absorption of the grafts. These observations, however, are at variance with those of other authors. Grant and Norcross,⁵ who have reviewed the literature on cranioplasty, observed 58 cases for periods of time varying from nine months to nineteen years after operation. Satisfactory results were obtained in 48 of these patients and absorption of the grafts was noted in only 3 instances.

Peer⁶ has recently stated that fresh autogenous rib cartilage is the most satisfactory cranioplastic material. He points out that it lives as cartilage as long as the patient survives. However, Grant and Norcross object to its use for this very reason. The defects, by remaining cartilaginous, are never solid. A second disadvantage, also applicable to the use of bone, is that satisfactory repair from the cosmetic standpoint is not always obtained, owing to the shape of these grafts.

In the discussion of the alloplastic methods the use of celluloid will first be considered. Ney has described 300 cases of cranioplasty in which this substance has been used. He reports only five failures in his unusually large series of cases. Furthermore, in 4 of these 5 cases the celluloid plates were successfully reinserted.

at a later date. The disadvantages of celluloid have been discussed by Grant and Norcross, who point out that it is a foreign body, is nonrigid and may become soft and ineffective. In 1 case in which they reoperated because of severe headache the celluloid plate was invested in a capsule several millimeters in thickness. This intense and progressive type of connective tissue response to celluloid has been demonstrated in experimental animals by Penfield.⁷

In 1941 Geib and later Beck and Peyton and Hall described the successful use of vitalium plates for the closure of cranial defects. The plates were well tolerated in all of Geib's 4 cases. His longest period of observation at the time of writing was two years. One of his patients died of an unrelated cause and at autopsy there was no evidence of an unfavorable reaction to the metal. Peyton and Hall describe a good clinical result in their case at the end of six months of observation. Beck reports the successful use of vitalium in 4 cases. He has overcome one disadvantage attending the use of this metal, namely the necessity of having the plates cast to fit the defect, by employing broad vitalium strips cast in several sizes. These can be bent to the desired contour at the time of operation.

In addition to vitalium and tantalum there are other metals which have been demonstrated to be comparatively inert in tissue. The various types of stainless steel have found a wide application in orthopedic surgery. More recently Campbell and his colleagues⁸ have shown that titanium is not cytotoxic either *in vitro* or *in vivo*. This metal is an alloy composed of nickel, cobalt, chromium and molybdenum, with a small amount of beryllium added if it has to be cast. However, to my knowledge, the use of these metals for the repair of cranial defects has not been reported.

Tantalum is an element, the seventy-third in the periodic table. It is a bluish white metal resembling steel in its physical properties and glass in its chemical characteristics. The ductility of tantalum enables it to be drawn into wire or rolled into sheet while in the cold state. It is this property which is of value at the operating table. Owing to its malleability flat tantalum sheet can be cut to fit the defect with tin shears or heavy surgical scissors and then hammered or bent to the desired contour. With regard to its chemical properties, tantalum is resistant to all of the inorganic acids except hydrofluoric and fuming sulfuric acids. Furthermore, it is resistant to weak alkalis, strong alkalis in weak concentrations and the salts, except those which hydrolyze to form strong alkalis.

Before I discuss the published experimental and clinical data on tantalum it is fitting at this point to mention the fundamental investigations of Bothe and his colleagues⁹ on the surgical metals. These workers have studied the reaction of bone to metallic implants. They conclude that the unfavorable reaction of the bone is due not to electrolysis but to the physical and chemical properties of the metal itself. Similarly, the unfavorable reactions to alloys are due to the presence of toxic metals, e. g. nickel, copper and manganese, in them. In their conclusions they point out that vitalium comes nearer to meeting the requirements of a surgical alloy than does stainless steel. Finally they mention that

tantalum may be the material of choice when sufficient data on this metal are available.

Burch and Carney¹⁰ were the first workers to use tantalum in surgery. They successfully employed bone plates and screws and wire in both animal and human tissue. This work has been confirmed by Burke¹¹ who was the first observer to publish results attending the surgical use of this metal. He was particularly impressed by the lack of reaction when tantalum wire was used as a cutaneous suture.

In collaboration with Odom I¹² have published the results of experiments in which tantalum foil of $\frac{1}{1000}$ inch thickness was used to protect cerebral wounds from the ingrowth of connective tissue and blood vessels from the overlying structures. In this study the metallic foil provoked a minimal encapsulation in connective tissue and was far superior to the other materials used. In another series of experiments¹³ the reaction to Cushing's hemostatic clips fabricated from tantalum ribbon was compared to that attending the use of clips cut from the standard silver ribbon. In this study only a slight marginal neuroglial reaction and/or minimal encapsulation by connective tissue occurred around the tantalum ribbon. In contrast the silver clips provoked an intense inflammatory reaction which eventually led to encapsulation in dense connective tissue. As a result of these findings tantalum clips have replaced silver clips in all neurosurgical procedures carried out at the Montreal Neurological Institute.

METHODS AND MATERIALS

Tantalum plates were implanted in the cranial defects of 11 cats. The operative procedures were carried out under sterile conditions using intraperitoneal soluble pentobarbital anesthesia. The scalp and underlying fascia were incised in the sagittal plane and retracted laterally. An incision was then made into the temporal fascia along its line of attachment to the calvarium. This fascia and the temporal muscle were reflected from the skull with a periosteal elevator. By this means a satisfactory exposure of the calvarium was obtained. The several types of cranial defects were made with a trephine and mastoid rongeurs. Tantalum plates $\frac{1}{100}$ inch in thickness were used in all the experiments with one exception.

Three separate techniques were used in the employment of the tantalum plates. In 6 cats bilateral trephine holes approximately 1.5 cm in diameter, were made. In these animals only one of the cranial defects was repaired with the metal. The tantalum disks were cut to fit and were supported in position by small spicules of bone projecting into the defect from the inner table of the skull. No other method of fixation of the plates was used. In a second group of 4 animals midline rectangular defects, approximately 2.5 by 1.5 cm, were made. In this group the tantalum plates were secured to the skull with two 35 gage tantalum wires, one on each side. In 1 animal a large round midline defect was made and covered with a disk of tantalum $\frac{1}{100}$ inch in thickness, which was bent to conform with the convexity of the surrounding skull. This was the only experiment in which the tantalum plate was used to cover, rather than fill, the cranial defect.

At the time of closure all bleeding was carefully controlled with the electrocautery. The temporal muscles were approximated to the skull with bridging sutures of silk extending across the midline. Interrupted black silk sutures were used to close the other layers, and a sterile dry dressing was applied.

Fig. 1 (cat 1).—Appearance of outer aspect of calvarium. Specimen taken after period of survival of one hundred and ninety seven days. The tantalum plate (T) has been reflected from the defect on the wire hinge. Note the inner layer of the connective tissue capsule (C).

The animals were killed after periods of survival varying from twenty-seven to three hundred and eighty days. There was no evidence of reaction to the metal during the observation period in any of the animals. In addition to occasional palpation of the site of implantation of the metal, roentgenograms of the skull were made, either during the interval phase or just prior to death, to determine whether any marginal necrosis of bone had occurred.

At the end of the survival period the animals were again deeply anesthetized with intraperitoneal soluble pentobarbital. The neck was incised and both internal carotid arteries and internal jugular veins were exposed. A cannula was inserted into one of the arteries and the head perfused with isotonic solution of three chlorides followed by 10 per cent solution of formaldehyde.

When the tissues were firmly fixed, the site of implantation of the tantalum plates was carefully

Fig. 2 (cat 1).—Appearance of specimen under transillumination demonstrating the thinness of the connective tissue lamina (C) and the marginal proliferation of bone (B).

exposed. Due care was taken to leave tissue relationships undisturbed. This was accomplished by removing the scalp and galea with sharp dissection, incising the temporal muscles and pericranium at an appreciable distance from the plate and cutting the bone and dura at the periphery. By this means the calvarium, with the overlying muscles and pericranium and the underlying dura attached was removed *en masse*. The specimens were preserved in 10 per cent solution of formaldehyde to await further study.

RESULTS

In all the experiments the tantalum plates were enveloped in delicate translucent layers of connective tissue which were continuous with the pericranium. The capsule was completely formed at the end of twenty-seven days and interestingly enough, showed no tendency to progressive thickening. Even at the end of three hundred and eighty days, the longest period of survival, the bluish white luster of the metal was easily perceptible through the delicate layers of the capsule. These layers were tightly adherent to the tantalum plates and intracapsular fluid formation was absent. The inner layer was adherent to the dura but easily separable from it. Finally, when the capsules were opened the lining was invariably found to be smooth and glistening. Certain of these characteristics are illustrated in figures 1 and 2.

The changes in the bone bordering the tantalum plates were of particular interest. Osteoblastic activity was not hindered and even at the end of twenty-seven days the proliferating bone at the edge of the defect had closely approximated the edge of the metal. In the animals surviving three hundred and seventeen and three hundred and eighty days there was a complete closure of the cranial defect by the new bone formation. This osteoblastic proliferation was confirmed by microscopic study. The osseous layer was so closely adherent to the tantalum plates that when the latter were removed an accurate bony impression of them remained (figs. 3, 4 and 5). Proliferation of bone over the external surfaces of the plates was absent in all instances.

Without exception the tantalum plates retained their original luster and showed no signs of corrosion. Finally an inflammatory reaction leading to extrusion or necessitating removal of the plates did not occur.

Fig. 3 (cat 2).—View of outer table of calvarium showing the site of the cranial defect (D). Specimen taken after period of survival of three hundred and eighty days. In this animal the cranial defect has been completely obliterated by the regrowth of thin lamina of bone beneath the tantalum plate. An osseous impression of the tantalum plate remains.

COMMENT

These observations on the experimental use of tantalum plates for the repair of skull defects have again confirmed the inertness of this metal in animal tissue. Furthermore, the studies demonstrate that tantalum is a satisfactory material for this purpose. There are several points of evidence in favor of these statements: 1. Although encapsulation of the metal in connective tissue occurred it was not progressive in character. This would obviate the possibility of local pressure on the brain by a steadily thickening capsule. Even after three hundred and eighty days the connective tissue envelop was thin, translucent and tightly adherent to the metal. 2. The presence of the metal did not interfere with the normal regeneration of bone. After approximately eleven months the cranial defects were closed by a thin osseous layer formed beneath the metal. 3. There was no corrosion of any of the tantalum plates. In their report on the use of tantalum for the repair of cranial defects, Peyton and Hall state that an ideal cranioplastic material should be (1) nonirritating both

electrically and chemically, (2) strong and malleable (3) light in weight, (4) nonabsorbable and (5) malleable. Tantalum fulfils all these requirements except that of lightness in weight. It has an atomic weight of 180.9, about three times that of iron. However, the ability to use a thin sheet of the metal compensates for this disadvantage. Furthermore, despite its heaviness none of the patients who have had a cranial defect repaired with tantalum have, to my knowledge, been aware of any sensation of heaviness or pressure.

Fig 4 (cat 2)—Appearance of inner table, confirming the closure of the defect with new bone (B)

Although no clinical reports on the use of tantalum for cranioplasty have appeared in the literature, the metal has been so used by several workers. Fulcher¹⁴ who was the first to use the metal for cranioplasty in clinical subjects, has employed tantalum sheet $\frac{1}{40}$ inch in thickness to repair rather large defects of 2 patients. Excellent results were obtained in both instances. Penfield,¹⁵ Cone¹⁶ and Spurling¹⁷ have had similar encouraging results. They have obtained the desired contour of the metal plates by hammering them either over convex surfaces or in concave molds. I would suggest the use of a rayhide mallet and a hollow wooden mold. The latter should be designed so that any desired degree of convexity is attainable. Holes can be drilled through the plates to permit wiring to the skull and the escape of any blood or cerebrospinal fluid which may collect beneath them.

SUMMARY AND CONCLUSIONS

These experimental studies indicate that tantalum is a satisfactory alloplastic material for the repair of cranial defects. It has the desirable qualities of noncorrosiveness, inertness in tissue, nonabsorbability, absence of toxic ingredients and malleability. This last quality enables the surgeon to form the flat tantalum sheet to the desired contour at the operating table. In view of these characteristics, the use of this metal should be considered in the repair of many of the cranial defects which will inevitably occur as a result of craniocerebral injury in the present war, and particularly in those repairs in which a satisfactory cosmetic result is of utmost importance.

THE TREATMENT OF ACUTE CHOLECYSTITIS

AN EVALUATION

MAJOR ROBERT ZOLLINGER

MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

COLONEL ELLIOTT C CUTLER

MEDICAL CORPS, ARMY OF THE UNITED STATES

The great variability of the clinical course and pathologic picture of acute cholecystitis requires the individualized treatment of this condition. This has not been common practice. Instead rigid and to a certain extent contradictory, plans of treatment have been recommended. These range from operating early as in appendicitis, to delaying surgery until the acute manifestations of the disease have entirely subsided. Both methods have much to commend them and no doubt have favorably influenced the treatment of this condition. This controversy however has not been without danger, since attempts to assimilate and apply the two methods have been confusing to the practitioner. In recent years at the Peter Bent Brigham Hospital each patient with acute cholecystitis has been treated as an individual surgical problem.¹ The results have been so satisfactory and the mortality rate so much improved that a restatement of our views and a clarification of the issues involved seems desirable.

The program which we have utilized is as follows. Regardless of how slight the signs and symptoms may be as soon as the diagnosis of acute cholecystitis has been established immediate hospitalization is urged. Acute cholecystitis is such a potentially serious disease that the idea of treating the patient at home has been abandoned entirely, and our results have justified this change. Early hospitalization does not necessarily indicate that early surgery will be carried out but affords an excellent opportunity to institute treatment which will prepare the patient for surgery at an ideal time.

The extent and severity of the inflammatory process in the gallbladder are estimated by physical examination plus an evaluation of the patient's general condition. The accepted conservative measures are then instituted: (1) relief of pain by morphine, (2) semisitting position with heat to the abdomen, (3) administration of fluids by the intravenous or subcutaneous routes to hydrate the patient properly and (4) constant gastric suction if the patient is vomiting or distended. Routine laboratory studies, including urine and blood examinations, are made.

Although many patients with acute cholecystitis respond promptly to treatment, the possible concomitant complications must not be disregarded and even in mild cases the signs, symptoms and laboratory data should be evaluated at frequent intervals. In severe cases this should be continued throughout the night. Obviously, this would not be practicable if the patient should be treated at home.

CLINICAL TYPES

We attempt to classify each patient clinically, i. e. in accordance with the duration and severity of the attack and the response to general treatment. This aids the

clinician to decide the subsequent course of treatment for each patient and to determine safely the optimum time for early or late surgery. There are at least three major clinical groups. The first group comprises the majority of patients, whose signs and symptoms subside after adequate treatment with rest, fluids and relief

TABLE 1—*Indications for Early or Delayed Surgery*

Early	
1	Good risk patient seen shortly after onset (24 to 48 hours)
2	Exacerbation of symptoms while under treatment
3	Progression of signs or symptoms while under treatment
4	Signs of generalized peritonitis
Delayed	
1	Patient seen late with decreasing signs and symptoms
2	Elderly or poor risk patients with decreasing signs and symptoms

of pain. These patients are sometimes well prepared for surgery within five or six days. However, many clinical variations of this group are encountered. For example, some patients present minimal signs and symptoms of acute cholecystitis—perhaps because the attacks have been mild or because the physician was not called until the acute episode had quieted down. We are convinced that it is safer to send these patients to the hospital, even if it is a first attack. They usually respond promptly to general conservative measures and can be operated on without undue risk within eighteen hours of admission. Other patients, with more pronounced symptoms, respond promptly to conservative treatment within forty-eight hours with the return to normal of their temperature, white cell count and physical findings. If operation is not carried out when the proper state of hydration is obtained, a few of these patients will have an exacerbation of symptoms after forty-eight hours. It is impossible to predict the course of their disease when treated conservatively, hence, early hospitalization and surgery are urged. Many other patients show slow but progressive improvement, with subsidence of acute manifestations after three days. Although we feel that it is best to operate early in these cases, we have not hesitated to delay operation when the progress is satisfactory.

The second group includes those patients whose temperature, white cell count and physical findings remain

TABLE 2—*Surgical Treatment*

		Number of Deaths	Mortality Per Cent
Total operations	146	4	2.6
Cholecystectomy	70	0	0
Cholecystectomy and choledochotomy	47	1	1.5
Cholecystostomy	28	3	10.7
Cholecystostomy and choledochotomy	1	0	0
Common duct stones removed		23	
Incidence of common duct stone		14.9%	

practically constant, with no response to initial treatment. Operation should not be delayed in this group and should be performed within thirty-six to forty-eight hours, after the fluid balance has been adjusted.

The third clinical group is made up of the small number of patients whose signs and symptoms show rapid progress. These patients are acutely ill and usually require simple drainage of the gallbladder as soon as possible.

TIME FOR OPERATION

As stated before, we attempt to individualize the treatment of each patient. It is very difficult to make fixed rules to govern the proper time for surgery in acute cholecystitis. However, an emergency operation is rarely necessary. Sufficient time should elapse to allow for proper hydration of the patient (table 1). By early operation we mean that which is performed within twelve to forty-eight hours after admission of the patient to the hospital. This is done under the following circumstances: 1 When the patient is a good risk and is seen soon after the onset of the attack, within twenty-four to forty-eight hours. 2 When the patient, progressing satisfactorily under conservative treatment, develops an exacerbation of symptoms. If the patient's physical findings, temperature and white blood count increase or sufficient distress returns to necessitate administration of morphine, operation should not be delayed. 3 When the signs and symptoms fail to respond to, or increase under, treatment. It is not unusual to find that these patients have an extracholecystic abscess. They are usually quite ill and sometimes it is best to do no more than a cholecystostomy. 4 In a small group of patients who are acutely ill with signs of generalized peritonitis, in all likelihood associated with acute cholecystitis. In some instances there may be a question of differential diagnosis between

TABLE 3—*Indications for Cholecystostomy*

- 1 Elderly patients or those accounted poor surgical risks who present a well defined mass
- 2 Seriously ill patients for whom minimal surgery is desirable
- 3 Presence of an abscess about the gallbladder
- 4 When technical difficulties prevent cholecystectomy

acute cholecystitis, acute appendicitis or perforated ulcer. These patients are first given fluids and then are operated on within a matter of a few hours after their admission to the hospital.

Operation is delayed and conservative measures are continued if the patient is seen forty-eight hours or more after the onset of the acute attack and the signs and symptoms have subsided under conservative treatment. It is our feeling that postponement of the operation for a few days is all that is necessary. We tend to delay operation on elderly patients if they progress satisfactorily under conservative treatment. Likewise, operation is delayed if a patient is a poor risk, because of a pathologic condition other than that related to the acute cholecystitis. It should be remembered, however, that in many of the groups that have been mentioned an exacerbation of symptoms may occur requiring early surgery. Furthermore, one must remember that occasionally the signs, symptoms and laboratory data are misleading and do not give reliable information as to the actual severity of the pathologic process involving the gallbladder. This is especially true among elderly persons.

CLINICAL ASPECTS

During the past five years we have operated on 146 patients with acute cholecystitis in the Peter Bent Brigham Hospital according to the plan of individualized treatment just outlined. Despite the fact that immediate hospitalization has been urged for these patients, we have noted little evidence of a trend in this direction. As a matter of fact only 45, or 30 per

cent, of our patients entered the hospital within forty-eight hours of the onset of the acute attack. This, no doubt, varies in different clinics. Allen and Wallace² found that approximately 85 per cent of their patients were admitted during the early period. Chart 1 shows the duration of symptoms from the onset of the acute attack until operation. This period is more important than the interval between admission to the hospital and operation. Only 7 patients were operated on within twelve to twenty-four hours after admission and a total of 15 patients were operated on during the first forty-eight hours. Relatively few of our patients, therefore, were operated on early after the onset of the attack. This was partly due to the fact that it seemed desirable to complete their preoperative preparation or perhaps because the symptoms had existed for a longer period of time when admitted. Considerable weight in favor of early operation may be drawn from the fact that there were no deaths among 57 patients operated on within eight days of the onset of an acute attack of cholecystitis.

Acute cholecystitis is primarily a disease of middle life. Our patients varied in age from 19 to 77 years

Chart 1—Duration of symptoms. Note that only 15 patients were operated on within forty-eight hours of the onset of the acute symptoms. Furthermore there were no deaths within eight days of the onset of symptoms.

(chart 2) Forty-five of them were less than 45 years old, in which group there were no deaths. As one would expect, it was primarily the older patients who died, all 4 being patients between 45 and 65 years of age. Yet we have never considered that advanced age in itself is a contraindication to surgery.² There may be a tendency to postpone or advise against operating on older patients having their first attack of cholecystitis. However, one cannot but be impressed after reviewing many case histories, that many of those could have been treated surgically with far greater safety.³ That the elderly patient can withstand cholecystectomy is illustrated by the fact that 31 of our patients were above 65 years of age and 16 of these above the age of 70. There were no deaths in this group.

The mortality among 146 patients with acute cholecystitis, having 156 operations on the gallbladder during the five year period from 1937 to 1941, was 2.6 per cent (table 2). Cholecystectomy was performed on 70 patients without mortality. This indicates the safety of removing the acutely inflamed gallbladder completely

in properly selected cases. In recent years we have practiced almost as a rule emptying the acutely distended gallbladder through a trocar. If the field is properly walled off, the danger of spreading infection is far less than the hazard of poor exposure. It must be remembered that only in about one half of the cases is it possible to obtain a positive culture, the inflammatory reaction in the remainder is due to chemical and mechanical causes.

On 57 patients choledochostomy was performed in addition to cholecystectomy with but one death. Twenty-three of these patients were found to have one or more common duct stones, making an incidence of 14.9 per cent of all cases. Formerly it was thought that since the cystic duct was frequently blocked by a calculus in acute cholecystitis it was unlikely that any stones escaped into the common duct. Our

experience over a period of years has indicated the opposite, as we have consistently found a 12 to 15 per cent incidence of common duct stones in these cases. It has been our feeling that exploration of the common duct has added little or nothing to the total mortality, provided the patients have been properly prepared for operation. If we suspect from the patient's history that a common duct stone may be present, we tend to delay

operation as long as progress is satisfactory in order that the inflammatory reaction about the common duct may subside. The technical procedures in this region can then be more easily and safely performed. Operation is also delayed if the history, physical examination or laboratory findings (high diastase values) indicate that acute pancreatitis is associated with the acute gallbladder condition.

Twenty-eight patients had choledochostomy with a mortality of 10.7 per cent. Removal of the gallbladder is obviously more desirable, but in a few cases it is better to rely on simple drainage.

The high mortality that is associated with this procedure reflects its use in the more serious cases. We believe that a tendency to perform a greater number of cholecystostomies has been partly responsible for lowering our mortality. In general, choledochostomy has been utilized under the fol-

Chart 2—Age distribution. Three of the 4 deaths occurred between the ages of 55 and 65 years. However there were no deaths among 31 patients operated on above the age of 65. Old age is not necessarily a contraindication to operation.

Chart 3—Deaths. Three of the 4 patients who died had been treated at home from seven to fourteen days. In case 1 the period of hospitalization was unduly prolonged.

³ Quigley T. B. Biliary Surgery in the Aged. New England J Med 221: 970 (Dec. 21) 1939.

lowing circumstances (table 3) (1) in elderly or poor risk patients in whom a well defined mass can be demonstrated in the gallbladder region, (2) in the seriously ill patients who obviously cannot stand a formidable operative procedure, (3) when an abscess is encountered about the gallbladder and the general peritoneal cavity is walled off and (4) when for technical reasons it would be extremely difficult to remove the inflamed gallbladder especially when the structures cannot be properly identified. It is better for the surgeon to drain the gallbladder if technical difficulties make him uncertain of the correct procedure. We advise that the gallbladder of such patients be removed within two or three weeks during the same hospital admission. However if the patient is elderly or a poor risk, this may be postponed indefinitely in the hope that he will encounter no further difficulty.

The incidence and dangers of perforation have contributed to the differences of opinion in the treatment of acute cholecystitis. It has been pointed out that, the longer the operation is delayed, the greater is the incidence of perforation with a resultant higher mortality rate. The perforation usually is sealed off by the adjacent structures and an abscess is formed in the region of the gallbladder. A free perforation with escape of the contents of the gallbladder into the peritoneal cavity is relatively infrequent. This danger is probably greater for patients who have had previous abdominal surgery with fixation of the omentum elsewhere. We have had 2 patients in the last five years with a free perforation. Both were subjected to early operation because of the signs of generalized peritonitis, and both recovered. As a rule, persistent pain associated with increasing local signs of inflammation implies that the gallbladder has perforated and that an extrahepatic abscess is forming.

Occasionally this has been unexpectedly encountered because the signs and symptoms were so mild. Therefore early hospitalization and frequent evaluation of the patient's progress are important if this complication is to be avoided and a low mortality maintained.

The incidence of complications associated with acute cholecystitis is high 24 per cent. The majority of these are associated with the pulmonary system. Wound infections were second in frequency.

There were four deaths among the 146 patients operated on for acute cholecystitis. It is of some significance that all 4 of these patients had had their disease at least eight days before operation (chart 3). Three of the 4 patients had had the condition for seven to fourteen days before entrance to the hospital and all were operated on within three days after admission to the hospital. One patient, however, was sent to the hospital within twenty-four hours and conservative measures were followed for one week. In retrospect we feel that this patient should have been operated on earlier. The cause of death of 3 of the patients was infection. One patient had an *Escherichia coli* septicemia, while another had a peritonitis due to the same organism. In addition to acute cholecystitis 2 patients had a stone located outside the gallbladder. One death was the result of a cranial intraventricular hemorrhage.

SUMMARY

The patient with acute cholecystitis should be hospitalized as soon as the diagnosis is established, regardless of how mild the symptoms may seem. It is a common and serious condition with possibilities that cannot be predicted except by frequent evaluation of

the patient's progress. Clinical groups based on the duration and severity of symptoms and their response to standard conservative measures provide a clue to the selection of the proper time for surgery either early or delayed. Sufficient time must be allowed to hydrate the patient properly and prepare him for operation. Rarely does a patient require emergency surgery. A mortality of 2.6 per cent was obtained over a period of five years in the surgical treatment of 146 cases of acute cholecystitis. The incidence of common duct stones associated with acute cholecystitis was 14.9 per cent. Our experience indicates that although early hospitalization is ideal from the standpoint of the patient, a low mortality can be obtained regardless of whether he is seen early or late, provided he is treated as an individual surgical problem.

ABSTRACT OF DISCUSSION

DR FRANK GLENN, New York. At the New York Hospital Dr Heuer and I have over the past nine years kept a careful account of patients we have treated for acute cholecystitis and we have adhered to a policy of operating on all after adequate preoperative preparation unless there is some contraindication. We have treated surgically 379 patients with acute cholecystitis. There have been no deaths in those under 40. Three deaths occurred in a group under 50, and the remainder occurred in patients over 50. It is in this group of patients over 50 that we most frequently see the complications associated with cholecystitis, and it is in this group that we see mortality occur regardless of whether they are treated medically or surgically. Individualizing should be encouraged. The adverse reports concerning the surgical treatment of acute cholecystitis are the result of inadequate preparation for operation, failure to recognize contraindications to surgical therapy and improper surgical technique. Our mortality rate in 379 cases of acute cholecystitis is 2.37 per cent and we may compare that with a group of 1176 nontumor cases in which the mortality rate was 2.71. Acute cholecystitis is essentially a disease of young adult life occurring most frequently in women of childbearing age. It may occur in younger and does occur in older persons. In the older it is almost without exception a complication of a long standing biliary tract disease. The common type of patients with acute cholecystitis is therefore a good surgical risk. They will in the majority of instances recover from the attack, as the authors have pointed out but they do so to enter later into the group that contribute to the mortality rate to biliary tract surgery today.

DR HENRY F. GRAHAM, Brooklyn. There are certain facts about acute cholecystitis that we should always keep in mind in every case. The first is that operation early in the disease, that is in young people is free from danger. Second that operation early in the acute gallbladder attack has a low mortality. We collected a group with a mortality in 167 cases of 3.9 per cent. In 1 of those cases there was an acute pancreatitis. Heuer sometime ago showed 112 cases in which operation was performed before perforation had occurred with a mortality of 1.8 per cent and the Postgraduate gallbladder clinic shows a mortality for acute cholecystitis without pancreatitis of 2.9 per cent. The third point is that no surgeon can determine the exact disease process present in the gallbladder by any clinical or laboratory examination. I have operated on patients who seemed to have no acute inflammation present and have taken out a gangrenous gallbladder. In the fourth place, infection is usually negligible during the first few days. Dehydration and other complicating factors are late manifestations of the disease. What operation to do in each individual case seen late is debatable and must be carefully considered.

DR D. W. BARROW, Lexington, Ky. In an analysis of 167 cases of acute cholecystitis recently made no other factor was so closely correlated with the mortality rate as the interval elapsing between onset of symptoms and hospitalization. Of the 167 patients, only one fifth 20.6 per cent came within twenty

four hours after onset of symptoms. The mortality rate in this group was 3 per cent, and, if the 2 patients who died following cholecystectomy through an incision originally intended for an appendectomy are excluded the mortality rate was zero. Of the patients coming to the hospital one to three days after onset the mortality rate was 6 per cent and of those coming more than three days, who formed more than half the series the mortality rate was 10 per cent. The patients in these groups were treated both by prompt operation after adequate preoperative preparation and by conservative measures. As far as we could tell the mortality rate particularly in the third group, was about the same when treated in either way which emphasizes the importance of bringing the patients to the hospital early before too great damage to the liver and body homeostasis has occurred. In this group of 167 patients there was no way in which the subsequent clinical course could be determined by any method available. Every patient with early acute cholecystitis, even though the initial manifestations may be mild should be considered as potentially seriously ill and measures including hospitalization intended to preserve physiologic function should be instituted promptly.

DR MOSES BEHREND, Philadelphia. I have never subscribed to the idea that an acute cholecystitis was an emergency operation. Patients with acute empyema of the gallbladder have a high mortality and should not be operated on immediately. I do not believe that so many operations of cholecystostomy are necessary in the treatment of acute cholecystitis. These patients must be hospitalized. Home treatment, such as the giving of food and water, are prohibited. Instead they are given intravenous fluids and fluids by hypodermoclysis. I take exception to the belief that one cannot tell clinically by palpation and physical examination and by the pulse and temperature whether or not the symptoms are subsiding. I like the term "opportunity time" for the operation, and the opportune time for these patients is the interval when all the symptoms of acute cholecystitis have subsided. They will subside if they receive absolutely nothing, by mouth. I do not fear perforation, because if these patients are hospitalized the complication is not a serious factor. If the gallbladder should perforate the patient can be operated on immediately. At operation there is not any mechanical difficulty in recognizing the structures during an attack of acute cholecystitis if the symptoms and signs are allowed to subside. This is one of the reasons why I have not performed a cholecystostomy for at least ten years in these acute cases. With the use of a long handled knife it is easy to cut along the peritoneal covering of the common duct, cystic duct and the gallbladder itself, then by teasing the peritoneal structures away with a curved scissors—blunt, not pointed—the structures around the foramen of Winslow can be definitely recognized.

DR ELLIOTT C. CUTLER, Boston. Like Dr Behrend I believed one could withhold surgery until most of these patients got well. The trouble is that the mortality figures under those circumstances were more than double those we now present. Only when we carried out cholecystostomies on these critically ill, elderly people and people with burst gallbladders or seriously incapacitated poor risk individuals did our mortality rate remain high. A low mortality requires individualization of every patient. We have been through just the same thing in appendicitis. We are reaching the same philosophical attitude toward the biliary tract as a whole. Each case is different. I am satisfied that our mortality has been improved and I am satisfied that a large percentage of the improvement was due to numerous cholecystostomies, much as I despise that operation. Two days ago a man came into the hospital with intestinal obstruction and vomiting. He had been sick for ten days. We gave him an Abbott-Miller tube inflated him and the gallbladder was blown off free. I wasn't going to tackle a poor risk patient who had a blown off gallbladder and a peritonitis by trying to take the gallbladder out. I sewed the tube in and left his gallbladder, and he made a prompt recovery. He may have to have his gallbladder out but he will be alive. I would reemphasize the need for individualization. In those who seem to be doing pretty well one can wait and do an operation of election in three to six days but if they don't improve steadily and rapidly one had better perform an operation.

THE PHENOMENON OF 'BLACK DERMOGRAPHISM'

ERICH URBACH, M.D.

AND

DONALD M. PILLSBURY, M.D.

PHILADELPHIA

The term 'black dermographism' designates the fact that under certain conditions a well defined black line appears where the skin is stroked with certain metals.

This phenomenon was first reported by the Russians Lmdin and Kusmenko¹ in 1925. They contrasted the well known red and white dermographisms with black dermographism and stated that only the latter was to be regarded as a true one i.e. actual writing on the skin, since both the white and red dermographisms are due to stimulation of the nerve and muscle fibers of the blood vessels of the skin.

According to these authors the black writing which appears on the skin following application of certain blunt metallic implements with moderate pressure represents not a chemical but a physical process due to the particles of the metal rubbed off by friction and remaining on the skin. While they originally assumed that a hysterical condition was a necessary prerequisite for the phenomenon Lmdin later retracted this idea.

TABLE 1—Metals Producing Black Dermographism on Prepared Skin

Copper	Positive	3
Aluminum	Positive	3
Nickel	Positive	
Zinc	Positive	
Tin	Positive	1-15
Gold	Positive	1
Brass	Positive	1
Cold (fine than 18 carat)	Positive	3

Breitmann² was the next to study this phenomenon. He observed that the black dermographism appeared not only in women who used face or body powder but also in factory and dock workers who had never used powder in their lives. Furthermore Markow, Berlin and Minkina³ have pointed out that an especially high incidence of black dermographism is encountered among workers engaged in particularly dusty occupations (cement mixing, stucco work and the like). Breitmann² advanced a chemical theory and held that the appearance of black dermographism is dependent on the character of the skin lipoids. He was of the opinion that finely dispersed particles of the metals are deposited in the upper layers of the skin as the result of some unknown alterations of the lipid metabolism of the skin. Breitmann based this assumption in part on the observation that the black lines will not appear when the skin is washed with alcohol or ether thereby temporarily removing the skin lipoids. Moreover, this author supposed that the phenomenon usually appears in association with some endocrine disturbance, especially of the thyroid gland.

80% fine gold	60% fine gold
15% copper	31% copper
5% silver + zinc	9% silver + tin

the phenomenon occurs chiefly in neurotic persons as well as in patients with organic conditions.

The German school of thought (Hauck and Dietel⁸, Krantz,⁹ Hosp,¹⁰ Bork,¹¹ Dietel,¹² Joch,¹³ Riehl¹⁴), on the other hand, adhered strictly to the pure physical explanation. Goldschlag¹⁵ and Koga¹⁶ also subscribed to this view. Hauck and Dietel⁸ emphasized however the necessity of differentiating between a "true" black dermographism which occurs without any previous preparation of the skin, as they claim in only a small percentage of human beings (27 per cent), and that type which can be produced at will in any one by the preceding application of zinc oxide. Hosp¹⁰ reports that he was able to produce positive results in every one tested under suitable conditions, even in corpses. Finally, it is of interest to note that the phenomenon can be produced not only on the human skin but also on filter paper⁹ and cloth.¹⁴

ORIGINAL INVESTIGATIONS

The phenomenon of "black dermographism" can under certain conditions be regularly evoked with the use of a number of different metals (figs 1 and 2). It should be noted at this point that in order to produce the black lines on paper (fig 3), cloth, wood and occasionally on human skin it is sometimes necessary to perform as many as six heavy strokes on the same line. The metals capable of producing a positive reaction on a powdered skin are listed in table 1, metals tested and found incapable of evoking this phenomenon are listed in table 2. Gold occupies an intermediate position: gold finer than 18 carats belongs to group 2, while gold less fine than 18 carats belongs in group 1.

This is probably due to the higher copper content of the lower grade gold (table 3).

Most of our experiments were performed with a half-dollar coin of a gross weight of 192 grains, consisting of 173.61 grains of silver and 19.29 grains of copper. However, numerous tests made at random have shown that all the metals mentioned in table 1 constantly react in the same manner.

The phenomenon of black dermographism can be evoked only when the skin, paper, cloth or other surface is dusted with certain inorganic powders as listed in table 4. Table 5 presents a list of those inorganic powders which do not evoke dermographism.

Lastly, table 7 presents a summary of all chemicals tested. It shows that with the exception of tin and titanium salts, which constantly produce positive results, and of bismuth and silver salts, which regularly give negative findings, all other metals include both positive and negative compounds. Thus some salts of calcium, magnesium, potassium, sodium, zinc, copper, silicon and so on constantly produce positive, while others of the same metals give negative, results. The response to a given salt is always the same regardless of the metal used in stroking if carried out on the same surface (skin, paper, and so on). However, not infrequently a given substance will produce a negative reaction on the skin and a positive reaction on coarse paper (table 7). This may possibly be explained by the highly hygroscopic nature of some compounds, which are able to absorb even the slight moisture of a clinically normal skin, thus tending to obviate the friction.

Regarding face powders, it should be pointed out that any kind—cheap or expensive—permit the elicitation of black "writing." Twenty well known brands of face powder were tested in this respect. Face powder consists principally of finest talcum, titanium dioxide, magnesium stearate, calcium carbonate, insoluble lake colors and synthetic perfume. Of these ingredients titanium dioxide and calcium carbonate make for strongly positive reactions.

Dust, notably street and factory dust, is also capable of preparing the skin for black dermographism.

Despite many consultations with chemists, physicists and metallurgists, we have been unable to set up any

kind of principle according to which it might be predicted whether a given inorganic powder will or will not give rise to this phenomenon. Although it is true that organic compounds practically never produce positive results (sodium oxalate being an exception), it is equally true that many inorganic salts consistently fail to produce reactions. The most obvious explanation is of course the varying degrees of hardness of the powdered substances. While we accept this explanation there are several apparent exceptions: iron carbonate

(hardness 4) and zinc carbonate (45) produce negative results with silver and copper, while iron sulfate (2) and barium sulfate (3) bring on the phenomenon. Although these exceptions cannot be accounted for on a single basis, two possible sources of error should be mentioned: (1) one chemical or another, despite due care, might have contained small amounts of impurities capable of altering the hardness, (2) the references regarding the degree of hardness of ordinary chemical compounds not used in the metallurgical industry are difficult to obtain and often quite old and at variance.

Table 6 shows how differently the various salts of the same metal used in preparation of the skin react, even such closely related compounds as sodium sulfate and sodium sulfite, for example. We would stress that, with the exception of sodium sulfite, all sulfur compounds react negatively and that therefore the sugges-

high moisture content of their skins as well as to the unusual thinness of the epidermis. The skins of these animals regularly fail to react in this manner even when covered with those inorganic powders which bring on

TABLE 7—Summary of the Chemicals Tested for Black Dermographism

Metal	Substance Tested	Reaction	Hardness
Aluminum	Aluminum hydroxide	Positive	2
	Aluminum sulfate	Negative	
	Aluminum silicate (fullers earth)	Negative	
Barium	Barium sulfate	Positive	3
	Barium oxide	Positive	
	Barium sulfide	Positive	
	Barium iodide	Negative

tion that black dermographism might be due to a sulfur compound (e. g. silver sulfide) may be promptly dismissed.

Hygroscopic and crystalline powders are ineffective in these experiments. Furthermore, results are always negative when the experiment is performed on a smooth, slippery surface, such as damp skin due to perspiration or wetting, greasy skin, glass or smooth, shiny paper. This is due to the fact that the nature of these surfaces eliminates friction, and physical junction of metal and powder is thus prevented.

When any of the powders listed in table 4 are applied to greased skin, the immediate reaction is negative, after some time (from half an hour to three hours), however, the reaction becomes positive if the powder has absorbed the fat. Similar observations have been made on skin areas sprinkled with water or damp with sweat, as soon as the powder has eliminated the moisture, the black lines can again be made to appear. Failure of the black dermographism to appear on the skins of animals including cats, rabbits and guinea pigs is probably due largely to the relatively

very strongly positive results on human skin. The importance of the relative thickness of the horny layer can also be observed in human beings. Thus it has been shown that the black lines can be evoked especially readily on the volar surface of the hand, where the

horny layer is as a rule particularly well developed. It is generally more difficult to produce a reaction on a naturally oily skin than on a dry skin. It may be said, in short, that the result depends entirely on the amount of friction when little pressure is exerted, far fewer particles can be rubbed off the metal by moist or greasy skin, or other smooth slippery surfaces (glass, shiny paper) than by skin with a rough, dry surface.

The black line can readily be washed off with water or rubbed off with a cloth. It is generally possible to cause the reaction to reappear after a short time. However, when a skin area previously treated with zinc oxide is cleansed with benzine or some other fat solvent or is washed thoroughly with soap and water the phenomenon cannot be brought on again unless zinc oxide is reapplied to the skin. When the black line is removed

strated that the chief constituent of the black line was silver in instances in which the phenomenon had been evoked with a silver coin (fig 4) and copper (fig 5) when copper metal was used. This conforms perfectly with the fact that minute black particles can be seen

Fig 1 — Black dermographism on skin dusted with zinc oxide using a silver coin

with ethyl acetate or benzene and the same sponge is rubbed over the unpowdered skin of a control subject the black dermographism can be evoked by striking the site with a metal. This is undoubtedly due to the transfer of some of the powder in the fat solvent medium, for the phenomenon cannot be evoked in this manner when the black line is rubbed off with plain water. Cleaning the coin with alcohol, ethyl acetate and the like does not prevent the appearance of the black line.

Since the possibility has to be considered that the fineness of a given powder might be the determining factor with regard to this phenomenon, experiments were undertaken with colloidal zinc oxide (granule size 1 micron). The results obtained with this substance were identical with those obtained with a coarse grained powder of the same compound.

Dr J. W. Lentz made photospectrometric examinations of the black line produced by rubbing a half dollar and pure copper on pieces of filter paper previously sprinkled with various inorganic powders. He demon-

Fig 2 — Black dermographism on skin dusted with titanium dioxide using a silver coin

when the skin is examined with a lens. It is certain, we believe, that the black lines are caused by metallic deposits.

COMMENT

Is the black dermographism to be regarded as a chemical or a physical phenomenon?

On the basis of the following facts we are convinced that this is strictly a mechanical and not an electro-lytic process. 1. Black dermographism occurs only in association with the use of those powders, salves and pastes leaving on the skin paper, cloth or wood powder residues which are harder than the metallic substance used for the "writing." 2. The harder the powder the harder the metal which must be employed to evoke the black line on a suitable surface. For example, iron with a hardness of 4 to 5 does not "write" when zinc oxide (4.5) is used but brings out the black lines following application of extremely fine sand (hardness 7). 3. A considerable amount of friction is neces-

Fig 3 — Black dermographism on paper towel dusted with zinc oxide using a silver coin

sary to produce the black lines. Mere pressing of the metal does not suffice, nor does gentle rubbing. The mechanical theory receives additional support from the facts that the manifestation appears immediately at the site of the stroke, that the skin must be dry for the phenomenon to occur, that the same result (black lines)

is obtained from the use of a variety of metals and of powders of various colors (white, yellow, purple) and that it is possible to demonstrate the presence of the metals (silver, copper and others) in the black lines by means of photospectroscopic or chemical analysis.⁵

Just why almost all organic and many inorganic powders fail to bring on the reaction is not as yet fully understood. This can be partly explained by their relatively low degree of hardness, particularly of the organic compounds, and also perhaps by the fact that these powders readily absorb water and thus tend to prevent the occurrence of the phenomenon by taking up some of the moisture in the skin, thereby diminishing friction. This view would seem to be supported by the observation that certain powders react negatively on the skin but positively on paper.

Is the black dermographism actually a form of dermographism?

Cases of red, white, yellow (Schurer,¹⁷ Adlersberg and Perutz¹⁸) blue (Koschewnikow¹⁹) and purpuric (Macleod²⁰) dermographism are erroneously so called because in these instances the appearance of the "writing"

visual differences due largely to variations in the moistness and oiliness of the skin. The phenomenon will appear in all persons with dry, nonoily epidermis. The former assumption that hysteria, neurasthenia or endocrine disturbances play a role has to be rejected. The fact that the phenomenon can be evoked in the skin of a corpse conclusively demonstrates that this process cannot be regarded as a biologic reaction.¹⁰

SUMMARY

Black dermographism connotes the fact that under certain conditions a black line will appear at a skin site stroked with certain metals. Black dermographism not infrequently occurs in women wearing silver or cheap gold jewelry on powdered skin areas.

Black dermographism is a physical phenomenon. The earlier theory that it is of some biologic or diagnostic significance is erroneous.

Strictly speaking the term "black dermographism" is a misnomer, since the reaction can be evoked not only on the skin but also on coarse paper, cloth and wood.

422 Medical Arts Building

Fig. 4—Spectrogram of a filter paper dusted with zinc oxide and stroked with silver coin showing heavy deposit of silver in the black line.

Fig. 5—Spectrogram showing quantitatively the increase of copper (two hundred times more than that of the control) after a filter paper dusted with zinc oxide is stroked with copper.

ing' is due to certain responses in the cutaneous blood vessels and not to reactions of the surface of the skin itself. On the other hand, the designation "black dermographism" is incorrect, strictly speaking, since the writing takes place not on the epidermis per se but really on the powder dusted on the skin. Proof of this lies in the fact that the same effect can be produced on coarse paper, linen cloth, wood and other rough surfaces.

Black dermographism is not infrequently observed in women who wear trinkets and cheap jewelry of silver and gold on powdered areas. The same effect occurs on skin surfaces soiled with street factory or mine dust.

In principle the phenomenon may be evoked on any human skin by the use of appropriate inorganic powders. It must be noted however that there are indi-

ABSTRACT OF DISCUSSION

DR. SAMUEL M. PECK, New York: I thank the authors for clearing up many questions which I had about this condition in years past. It seems strange that it had not been reported previously in American literature. We meet this phenomenon in our clinical practice frequently. How often have most of us had patients come to us for some other condition and say, "You know I have too much acid in my system. All my rings are turning black on my skin. When they consulted me about what they should do about this I was at a loss either to give them an explanation for the phenomenon or to offer any suggestions which might be of use. As has been pointed out the term dermographism should be dropped because we are not dealing with an urticarial phenomenon and since the whole process is probably on a physical basis I have noted in a number of my patients that they do not always show this black writing on the skin under apparently similar conditions such as wearing the same sort of jewelry and using the usual cosmetics and toilet soaps. In a number of cases the skin under wedding rings would turn black. This phenomenon occurred only at certain periods in their menstrual cycles. While I believe that this might be due to a difference in the dryness or moisture of the skin this physical condition of the skin was influenced indirectly by the endocrines and therefore might then be said to be on a glandular basis.

20. Macleod, J. M. H. Diseases of the Skin. London: H. K. Lewis & Co., 1920.

DR NELSON PAUL ANDERSON, Los Angeles This phenomenon was described in the English literature under the term of "metallic writing" at least over fifty years ago (Ferrier, David Note on a Peculiar Condition of the Skin in Paraplegia, *Brit M J* 1 341, 1879) The first observation that was made was on patients who had a cerebral hemorrhage The subsequent edema on one side of the body presented metallic writing on that side, while the other side of the body did not present such a phenomenon The first investigators in England thought that this was due to some chemical change in the skin Later they made further investigations, which I believe included most all of the metals that Drs Urbach and Pillsbury have mentioned

DR MARION B SULZBERGER, New York Dr Anderson has pointed out that the fact that metals will sometimes produce black marks on the skin has been known for a long time However I think that Dr Urbach and Dr Pillsbury contribute something of great interest when they show, not that metals will write on the skin, but the important role which certain powders at the skin surface play in producing this form of writing In other words, many of the cases that may have been previously considered to be due to peculiar changes in the sweat and in the chemistry of the skin surface and which were sometimes even explained away as due to stigmatization and hysteria may simply be produced by the powder on the surface of the skin

DR PAUL E BECHET, New York In my library there is a monograph in French of four or five hundred pages, published some sixty years ago, solely on the subject of dermographism The book contains a full chapter on black dermographism and what is of great interest, many paragraphs of that chapter are devoted to the important role played by black dermographism in demonology, black magic and witchcraft, which caused so much torture and burnings at the stake in the Middle Ages There is no question of a doubt in my mind that many ordinary dermatoses because of their mistaken association with leprosy, demonology and witchcraft have caused the torture, violent death and social excommunication of hundreds of innocent persons who were unfortunate enough to be born in the ignorant ages

DR ERICH URBACH, Philadelphia I would be much indebted to Dr Anderson if we could get the reference, because we took the pains to consult the ten best known dermatologic textbooks in the country, and we found the name 'black dermographism' or something of this sort only in the book by the Suttons All the other books do not mention it at all and therefore we are not familiar with the term "metallic writing" and would like to know more about it Dr Sulzberger's observation is more interesting than ours, but it would need some explanation whether it is chemical or physical Referring to Dr Bechet, I have not mentioned that in Europe this kind of black dermographism was used quite often as magic in order to deceive people I remember this kind of amusement very well when I was a boy A man would come out and say 'Now write your name on me' and this, of course, made a very deep impression on all the people

Intellectual Honesty—Two million soldiers and sailors in training centers and in stations in the tropics are living under sanitary controls that are far beyond anything that most of them ever knew existed Other millions are learning the principles and practices of first aid in case of injuries and tens of millions are taking keen interest in problems of diet Demands in the armed services, in sanitation and medicine, in industry and agriculture for young men and women with scientific training are far beyond the capacity of educational institutions to supply To carry on almost any of the work of the world in the future some kind of serious scientific training will be necessary, with the result that the uses and the methods of science will always be in the minds of people and often also the clear thinking and the intellectual honesty it requires—Moulton, F R Science and Technology, *Am A Advance Science Bull*, July 1942, p 34

TUMORAL CALCINOSIS

ALBERTO INCLAN, MD

WITH THE COLLABORATION OF DR P LEON AND
DR M GOMEZ CAMPEJO PATHOLOGISTS

HAVANA, CUBA

Under the name tumoral calcosinosis I am presenting 3 unusual cases of a calcified growth of unknown etiology and pathogenesis to which I have found but little reference in a careful search of the medical literature. All 3 patients with this condition have been treated at the Mercedes Hospital in Havana 1 having been seen in the cancer service and the other 2 in the orthopedic service It is interesting to note that all 3 of the patients are Negroes and that they live at points far distant from Havana and from one another

CASE 1—P Q A Negro girl aged 18 years first seen Oct 17, 1934 complained chiefly of pain and of a tumor in the left gluteal region Her story was that two years earlier she had suffered a fall, receiving a blow on the left gluteal region She attached no importance to her injury, which was

Fig. 1 (case 1)—Appearance of the left gluteal region before operation

in no way disabling Shortly before being seen however, she began to notice slight pain on sitting and a swelling at approximately the site of her previous injury Physical examination was largely negative except for the condition in the left gluteal region This region appeared decidedly prominent but without color changes of the skin There was no venous dilatation nor local increase in temperature Palpation revealed the presence of a large hard mass of bony consistency This mass was smooth rounded and attached apparently to the ilium Roentgenograms showed a dense osteochondromatous shadow superimposed on the shadow of the ilium The central portion of the shadow was of great density contrasting with which there was greater permeability of the marginal portions (the lateral view) Routine laboratory studies were made, revealing a slight anemia and a leukocyte count of 14,000 with an essentially normal differential count A diagnosis of giant osteochondroma of the ilium was made and operation was advised

On December 19, under spinal anesthesia, I made a long incision along the iliac border, planning to reflect away the gluteal muscles and reach the point of attachment of the tumor to the bone However, I was greatly surprised to find the external iliac fossa uninvolved and a huge tumor mass of bony

Read before the Section on Orthopedic Surgery at the Ninety Third Annual Session of the American Medical Association Atlantic City N J, June 10 1942

consistency within the muscles themselves. I therefore made a second incision in the midline of the gluteal region and perpendicular to the first incision, reaching the tumor as soon as the fascia was divided. There was no plane of cleavage, all three gluteal muscles and their bursae being involved, so that I began doing a massive resection, starting from the

Fig 2 (case 1) —Shadow on left ilium similar to giant osteochondromatous tumor

inferior portion of the tumor. At this point I found the sciatic nerve compressed by the tumor. When it was incised, this tumor proved to be different from any I had ever seen, being composed of numerous cells or cavities which were filled with a white, milky, dense liquid somewhat like magnesia magma, which I took to be colloidal calcium. In other portions of the tumor the muscle was infiltrated and apparently affected by a more advanced calcifying process. These portions had a putty-like consistency and gave a gritty sensation on being cut. The two pathologic types alternated with each other in different portions of the mass which involved all the gluteal muscles, sometimes showing large cystlike deposits of the

Fig 3 (case 1) —Cut section of the gluteal tumor showing large compact calcareous deposits

aforementioned milky substance. The blood supply was meager. I resected about half of the tumor, closing the skin and leaving a small drain at the most dependent portion of the incision for it was rather difficult to occlude the large cavity that was left after the tumoral mass had been removed. This portion of the wound healed slowly, drawing serous exudate containing amorphous calcium salts for a period of two weeks.

Because of the unusual findings at operation I carried out some complementary investigations on the patient. A Mantoux test, chest roentgenograms and determination of the sedimentation rate which were all normal helped to rule out tuberculosis. Various bacteriologic studies of the liquid found within the tumor proved it to be sterile. The blood calcium was 11.4 mg, the phosphorus was 4.7 mg and the phosphatase level was 3.28 Bodansky units. Chemical studies of the liquid showed the presence of calcium carbonate.

The pathologist's report was as follows:

Gross Examination—The tumor was a hard mass which, when cut, appeared to be composed of large cavities full of a white milky fluid resembling colloidal calcium.

Microscopic Examination—Slides were obtained by routine methods without previous decalcification. The tumor mass was composed of large calcareous deposits separated from one another by thick fibrous connective tissue trabeculae. The connective tissue found in the trabeculae was dense and fibrous, that found in the thinner trabeculae showing hyaline degeneration. The walls of the cavities were rich in hyaline degeneration and foreign body giant cells. The macrophages contained lipid substances. Toward the periphery histiocytes charged with lipid substances were seen and the vessels showed perivascular lymphocytic infiltration.

Fig 4 (case 1) —Section of one of the large calcareous deposits under low power magnification limited by thick bands of fibrous connective tissue

The patient received high voltage roentgen therapy following her operation, the remainder of the tumor diminishing in size after this treatment. Seven years after the operation no new calcified tumors have appeared either in the viscera or in the periarticular structures, which speaks against the possibility of this condition being a generalized calcosinosis.

The diagnosis of neoplasm, either benign or malignant, may be eliminated. A careful search for parasites was made, though trichinosis is extremely rare in Cuba, and none were found in the numerous cut sections which were made and studied with a microscope. Myositis ossificans was also eliminated clinically, roentgenologically and microscopically.

CASE 2—E. A., a Negro youth aged 19, first seen by my associates and me Sept 17, 1935, complained chiefly of swelling and severe pain in the left hip. He stated that two years before without suffering any injury he began to notice a hard swollen area in the upper part of the left thigh which later spread proximally toward the hip joint and iliac crest. Pain was severe from the onset and seemed to be worse at night, keeping the patient awake. Walking did not aggravate the pain nor did he notice limitation of motion at the hip, but he tired easily, so much so that he had to abandon his work.

Physical examination was negative except for the condition of the left hip and thigh. There was decided prominence of the posterolateral portion of the left thigh proximally, the circumference of the limb at that point being 60 cm as compared to 49 cm on the opposite side. No changes in the color of the skin and no prominent veins were visible. Palpation

Fig. 5 (case 1)—Section of the calcareous globules which made up the characteristic deposit of the tumor and the connective tissue network (Rio-Hortega medium power magnification silver carbonate stain)

revealed the presence of a large hard tumor which appeared to be fixed to the underlying tissues but not to the skin. A similar tumor about the size of an orange was found in the sacral region. The skin over the second tumor appeared lighter in color and was adherent to the tumor mass. The most prominent portion of both tumors appeared soft and fluctuating. Roentgenograms showed the presence of extremely dense shadows with indefinite margins in the left trochanteric and gluteal regions and a cylindrical dense shadow over the sacrum. Similar dense shadows though of lesser size were seen in the periarthritic structures of the opposite hip. Examination of the stool revealed the presence of ascaris hook worm and tricocephalus ova but there was no occult blood. The Kahn and Weimick reactions of the blood were negative and the blood count was well within normal limits.

The fluctuating portion of the sacral tumor was aspirated and 2 cc of an odorless, thick milky fluid was withdrawn.

Fig. 6 (case 1)—Showing the intimate contact between the calcareous globules and the connective tissue network (Rio-Hortega high power magnification silver carbonate stain)

Chemical studies of this liquid showed a high albumin content and the presence of calcium carbonate in suspension. Microscopically amorphous calcium crystals but no cells or bacteria were seen. Cultures showed no growth and animal inoculations gave negative results.

A biopsy of the gluteal tumor was done which grossly showed the same pathologic type as that seen in case 1, I then

extirpated the sacral tumor. The latter appeared to arise from the areolar connective tissue found between the aponeurotic origin of the latissimus dorsi and sacrospinalis muscles and the sacrum. This tumor was removed together with the adherent skin, and lateral skin flaps were mobilized and brought across to close the defect.

I have been unable to have the patient come back for reexamination, though I have ascertained that he is alive nearly seven years after the operation and nine years after the onset of symptoms.

The pathologic report on the excised tumor was as follows:

Gross Examination—The specimen was a rounded mass doughy in consistency, the size of an orange and covered by skin on three fourths of its surface. On incision the tumor was found to be composed of cystic cavities, varying in size from 0.5 to 3 cm which contained a white milky fluid. The walls of the cyst were smooth well defined and clearly demarcated from the surrounding fibrous connective tissue.

Microscopic Examination—Sections through the borders of the cysts showed large calcareous deposits which rested on an ill defined cellular stratum in which numerous histiocytes and foreign body giant cells were seen. Under higher magnification an intense fibroblastic reaction was visible and also foamy plasma cells similar to those seen in xanthomas. The polymorphonuclear giant cells were seen to contain calcareous inclusions. Ovoid double refractory bodies staining deeply

Fig. 7 (case 2)—Appearance of the tumor over the sacrum and the left gluteal region following biopsy of the latter

with the basic stains were seen occasionally at the edge of the cavity. These bodies did not resemble any phase of the life cycle of any parasite known to us. Beyond the wall of the cavity there was areolar connective tissue rich in blood vessels and containing lesser amounts of deposited calcium salts. The vessels showed endarteritis and perivascular lymphocytic infiltrations. Toward the periphery and away from the cavity bundles of degenerating muscle fibers separated by dense fibrous connective tissue were seen.

CASE 3—L. H. G., a Negro girl aged 10 years, seen by us on Dec. 5, 1940, complained chiefly of a tumor of the right elbow. The parents stated that three months previously they had noticed a swelling about 1 cm in diameter on the posterolateral aspect of the child's right elbow. The tumor was not painful and grew rapidly without producing local or systemic symptoms of any kind. Motion of the elbow joint was free and not painful. She was seen by her local physician, who treated her with massage for a few days, with further increase in the size of the tumor. She was seen at another hospital when the tumor was the size of an orange. Aspiration revealed the presence of a milky liquid. X-ray examination revealed a large calcified tumor at the level of the lower end of the humerus. Laboratory examination revealed coagulation time normal, calcium 10.9 mg, urea 27 mg and dextrose 90 mg per hundred cubic centimeters. The Kahn reaction was negative.

A urinalysis showed numerous pus cells and renal pelvis cells in the sediment.

Physical examination was essentially negative except for the right elbow, in which a tumor the size of half an orange was seen on its posterolateral aspect. The tumor mass projected outward on each side of the triceps tendon and its external portion was covered by distended shiny skin. Over this portion the tumor appeared soft and definitely fluctuating. The base of the tumor was hard and adherent to the epicondylar and epitrochlear muscular insertions. There was no increase in the local temperature or venous circulation and no regional lymphadenopathy. The position and shape of the tumor made me think that it arose from the subtricipital bursa, and the sharply outlined, very dense shadow led me to make a diagnosis of calcinosis or calcareous granuloma and decide on its removal.

The laboratory work done at our hospital revealed the following:

A blood count showed erythrocytes 4 250 000, hemoglobin 105 per cent, color index 1.02, leukocytes 8 000, lymphocytes 38 per cent, monocytes 2 per cent, neutrophils 54 per cent and eosinophils 6 per cent. The Kahn reaction was negative. Blood cholesterol was 232 mg, calcium 115 mg and phosphorus 41 mg per hundred cubic centimeters and phosphatase level 76 Bodansky units.

Under brachial plexus anesthesia an elliptic incision was made around the portion of skin which was adherent to the tumor. By blunt dissection the tumor was enucleated from under the triceps tendon which was found to be thinned out. The lateral portions of the tumor were calcareous and involved the epicondylar and epitrochlear muscles, from which it had to be carefully dissected in order that injury to the radial and ulnar

The pathologic report was as follows: This tumor was identical with that already described in case 1. The macroscopic appearance was practically the same although the tumor mass was smaller.

The patient was readmitted Jan. 14, 1942. She stated that six months after being discharged from the hospital she noticed

Fig. 9 (case 3)—A tumor of right elbow. B location of the new tumor of the left elbow and the aspect of the right elbow eight months after operation. C appearance following excision of tumors of both elbows.

a small, hard, nonpainful nodule on the outer aspect of her left elbow. This nodule grew rapidly during the succeeding months without ever being painful or interfering with motion at the elbow joint. Three months after the onset of the first tumor she noticed a similar nodule on the inner aspect of her right elbow. The latter grew slowly. Examination revealed the presence of a large hard tumor on the outer aspect of the left elbow very similar in appearance to the one seen on the patient's previous admission. A new tumor was not found at the site of the former operation on the right elbow but a small hard mass was present at the level of the ulnar groove below the medial epicondyle. There were no neurologic signs in the distribution of the ulnar nerve.

Laboratory work on admission showed erythrocytes 4 720 000, hemoglobin 65 per cent, leukocytes 13 000, lymphocytes 30 per cent, monocytes 2 per cent, neutrophils 68 per cent and eosinophils 0. The cholesterol was 225 mg, phosphorus 48 mg, calcium 9 mg and phosphatase 37 mg per hundred cubic centimeters.

The patient was given a course of a substance¹ which I have found successful in hastening reabsorption of calcified deposits in bursitis without any effect.

On March 13 I operated on the right elbow finding a tumor which was identical grossly with the one removed at the previous operation. The ulnar nerve was included in though not compressed by, the temporal mass and had to be dissected out carefully. The postoperative course was uneventful. The patient then received a second course of the substance¹ and high voltage roentgen therapy to the tumor of the left elbow without noticeable improvement. The tumor was then removed surgically on April 20. It was found deep to the triceps tendon and appeared to arise from the subtricipital bursa. No new tumors have appeared during the month of observation since her last operation. Her blood cholesterol on May 16 was 268 mg. Her general condition is perfect.

COMMENT

As I have said before, it is difficult to name and classify the clinical entity which I have just described and illustrated. Undoubtedly it is an atypical calcinosis which does not correspond to the types described by Steinitz and others,² namely all calcinosis

¹ Robes Anti Rheumatic Injection marketed by Robes Intravenous Products, Inc. called in Cuba Patogenol Gardier. It is stated to contain mercuri bichloride 0.9 mg, guaiacum solids 0.3 mg and sodium chloride 0.0066 Gm. per hundred cubic centimeters of 8 per cent alcohol (J. A. M. A. 86:1713 [May 29] 1926).

Fig. 8 (case 2)—Shadow of the gluteal tumor.

nerves might be avoided. The wound was sutured in layers and the elbow was immobilized in plaster for ten days, the operative wound healing by primary intention. Postoperative roentgenograms showed that practically the entire tumor had been removed. Chemical analysis of the liquid found within the tumor showed a high content of calcium phosphates and carbonates. Bacteriologic studies gave negative results.

circumscripta and calcinosis universalis. It is not similar either to Virchow's³ metastatic calcinosis. However, the microscopic aspect of the calcareous deposits and their chemistry do resemble those of the different forms of calcinosis which have been described. Geschickter and Lewis,⁴ studying tumors of the bursae, present 1 case in which the microscopic appearance is similar to that in my cases. A similar condition is described by Adrian as being reported by Milian and Neveu.⁵ This occurred in a woman aged 39, and the lesion was in the prepatellar bursa. Microscopically, the authors could find no tumor tissue and termed the condition calcareous granuloma.

Characteristics which may be of significance in my cases are that 2 of the 3 patients were female, all 3 were Negroes, there was a history of preceding traumatism in 1 case, there was a lack of symptom pain in 2 cases, there was absence of other calcifications in the skin, subcutaneous tissues, fascia and viscera and of changes in the skin, such as scleroderma, there was absolute articular integrity with no deformities, rigidities, contractures or disturbances in the gait, normal circulation and normal blood calcium and phosphorus were present, there was absence of localized or systemic infection, parasites were not found, the serologic reactions were negative, there were no tuberculous lesions and no skeletal deformities in the skull and thorax.

Only 1 case showed an increase in blood cholesterol, and it is to be regretted that more detailed specialized studies of the fat, calcium and phosphorus metabolisms could not be carried out.

I am of the opinion that my cases cannot be grouped under any of the conventional types of abnormal calcification such as myositis ossificans, metastatic calcinosis, calcinosis universalis and calcinosis circumscripta,

my cases as to symptoms, course and roentgen aspects. The predominating characteristics of my cases are the sign "tumor," the gigantic and progressive nature of the calcification, the spread of the growth beyond the muscular and bursal structures and the anatomic distribution to regions in which bursae and gliding cellular tissue are present.

Fig. 11 (case 3) —Tumor of right elbow

One cannot say with certainty whether the process begins in the bursae and spreads to the muscle or whether the reverse is true. However, in favor of the first hypothesis there is the fact that these tumors have always been found in regions in which bursae are commonly present.

The pathogenesis of this condition remains obscure, the explanations given by various investigators for the pathogenesis of calcinosis universalis and calcinosis circumscripta being in my opinion open to criticism.

The treatment in my cases has been surgical resection of the tumor, followed in 1 case by high voltage roentgen therapy. Owing to the local character of the lesion, I have not tried any of the methods of treatment advocated for calcinosis universalis.

According to Rothstein and Welt⁶ there is no specific treatment of calcinosis; medical treatment such as with solution of parathyroid, acetylcholine, insulin and pilocarpine as well as physical therapy, heliotherapy, roentgen therapy and even surgery being of little avail. Brooks, Craig and Lyall have used disodium hydrogen phosphate to mobilize calcium and increase its excretion, but this treatment has failed in the hands of Rothstein and Jacobowitz. Kennedy uses a ketogenic diet rich in fats, basing the rationale of his treatment on the observations of Frolich and Nelson that such a diet delays the union of fractures, but he has been unable to obtain good results. In other hands this treatment has also failed. Recently Ramsdell published the results obtained on 1 patient operated on more than 1 year before and presented 3 more patients with a syndrome of calcinosis treated by hemithyroidectomy and parathyroidectomy, with great improvement. The cases were typical of calcinosis universalis.

Fig. 10 (case 3) —Tumor of right elbow

which have already been described, for they differ from these clinically, roentgenologically and pathologically. Thirty-seven cases of calcinosis universalis reported in the literature by various authors bear no resemblance to

CONCLUSIONS

I have presented 3 cases of calcareous granuloma or tumoral calcinosis, not having found in the literature reports of any cases equal to these clinically, roentgenologically or pathologically

All 3 tumors occurred in the Negro race which may be mere coincidence, owing to the limited number of cases seen

In all 3 I found characteristically the presence of a calcified tumor, with rapid and gigantic growth, which apparently arose from a bursa and subsequently invaded the surrounding muscle

Resection and high voltage therapy have arrested, limited or cured the lesion

I have failed to determine the etiology of this interesting pathologic entity in the cases studied

Manrique 208

ABSTRACT OF DISCUSSION

DR ROBERT SCHROCK, Omaha This exhaustive study leaves us without suggestion as to what further might be done. The interesting feature is the close comparison which Dr Inclan and his collaborators brought out of this calcium material to the material that is practically always seen in calcinosis universalis, also their tie-up from an anatomic location to the regions where bursae normally are. I think they have come close to giving us an explanation of this through the tumors apparently originating in the bursae, then invaginating, as they emerge through the bursal sac, invading the surrounding tissue to this tremendous deposition of material, which apparently in all 3 cases is exactly similar. We are most appreciative of Dr Inclan's report

DR RALPH K GHORMLEY, Rochester, Minn. I had a case that is almost identical with Dr Inclan's second case and his third one. A boy aged 14 years came to the clinic six years ago. His immediate complaint was of a large tumor on one buttock which looked on the photograph to be almost identical to the lesion in the first or second of Dr Inclan's photographs. The roentgenogram showed a large, multilocular mass. We removed the tumor, which was a subgluteal bursa. It was multilocular. Many of the sacs were filled with a thick, heavy, calcified mass, almost pasty. Some of the sacs had thin fluid. Some of the fluid was slightly discolored, some of it was lemon colored and almost clear. The fluid was reported to contain mainly calcium phosphate. The boy had had another lesion on one elbow which had been excised by his home physician before we saw him. He went home and in a couple of years came back with another one on the opposite buttock. We went through the same procedure. These tumors weighed in the neighborhood of 4,000 Gm at the time of their removal. Later the boy came back for a research study and stayed with us for six weeks, during which time his calcium balance was studied by our chemists, who concluded that his calcium balance was normal. Nor did the roentgenologic studies show any evidence of decalcification of the bones, although we estimated that he had lost an enormous amount of calcium during the months we had him under observation. This boy had two sisters who had identical lesions. We found a similar case reported in a French journal of pathology in 1898. I believe this case was identical to ours and in this case too there was a familial history, two or three members of the same family had the condition. I don't know what the condition is any more than Dr Inclan does. I believe the lesions are bursae with an unusual tendency to calcify. In our case there was an interlying unusual deposit of lipid in the cells at the base of the bursa. This may or may not have had any significance. In our case too since the last tumor was removed we have been able to keep the boy from any recurrence by giving him small doses of sodium citrate, which procedure was suggested to us by a member of the medical staff.

DR ALBERTO INCLAN, Havana, Cuba. I appreciate the contribution of the discussers. I am not sure that these tumors come only from bursae, as the situation of 2 of these tumors was in places where there are no bursae. That is, I haven't

found any bursae described in those locations in the anatomic textbooks. I refer to the localization on the internal aspect of the elbow and the one in the sacral region this coming from the areolar connective tissue underneath the tendon at origin of the latissimus dorsi. These are the only places where we could be sure that these tumors arose, but there are no bursae anatomically known in those two places. On one of the microscopic sections shown we see the calcifications actually infiltrating the muscle fibers, suggesting that if the tumor arose from a bursa it certainly did not remain confined to its place of origin. These are the reasons why I hesitate in calling this tumor calcareous granuloma of the bursa or, as is suggested, to call it bursal calcinosis. In reference to Dr Ghormley's case, in none of my cases has a familial tendency been present.

PRIMARY LYMPHOID TUMORS OF THE
RECTUM RESEMBLING INTERNAL
HEMORRHOIDS

REPORT OF THREE CASES

CAPTAIN TOM E SMITH

MEDICAL CORPS, ARMY OF THE UNITED STATES

Owing to the fact that no report of a primary lymphoid tumor of the rectum resembling internal hemorrhoids could be found in the literature, it was deemed advisable to present 3 cases of rectal lymphoid tumors resembling internal hemorrhoids which occurred in my practice between January and June 1941.

There are numerous cases of primary rectal lymphoid tumors reported in the literature, but these cases have occurred in the rectal ampulla and not in the anal canal.

N. D. Smith¹ of the Mayo Clinic reported 1 case of lymphosarcoma in the anal canal but he made no mention of this tumor clinically resembling an internal hemorrhoid.

Kallet² of Detroit reported a myosarcoma of the rectum resembling an internal hemorrhoid, and this was the only report found in the literature in which a sarcoma was reported as clinically resembling an internal hemorrhoid. It is only natural to assume that if the muscle tissue of the anal canal could become sarcomatous it would likewise be possible for the lymphoid tissue to become sarcomatous.

In my series of three primary lymphoid tumors there were 1 case of lymphosarcoma and 2 cases of benign lymphomas.

The term lymphoma is used because it signifies a benign condition. Other terms have been used in the literature as synonyms such as benign lymphoid hyperplasia, giant cell lymphoblastoma and lymphadenoma.

There is much confusion regarding the nomenclature of lymphoid tumors as pointed out in an article by Hayes, Burr and Pruitt³. I have no desire to enter into this report the numerous arguments for different pathologic terms because of the possibility of increasing confusion. The reader is referred to the article by these authors for a classic discussion of the numerous terms and the arguments advanced by the proponents for the adoption of the several terms.

REPORT OF CASES

CASE 1—Mrs T L, aged 42, was seen on Jan 6, 1941 in consultation because of rectal protrusion. The protrusion had been present for "several months," so the patient stated, and on detailed questioning she said that the protrusion had been noticed for a period of from two to three months. There was inconvenience caused by the protrusion, but the patient stated that there was no anorectal pain, bleeding, discharge or itching. The patient referred to the rectal protrusion as the "piles."

Inspection, palpation and endoscopy revealed what was clinically diagnosed "second degree hemorrhoids." There was slight induration in the left lateral area, so it was thought that thrombosis was present. The right anterior and right posterior internal hemorrhoids were not unusual.

A hemorrhoidectomy was performed at St Paul's Hospital on January 8 and the tissue was sent to the hospital pathologist according to hospital routine for tissue examination.

The pathologist Dr Jack Goforth reported "hemorrhoids" and "rectal lymphosarcoma grade IV, radiosensitive" (figs 1 and 2).

After numerous consultations and a complete roentgen study by Dr Glenn Carlson, no other foci of lymphosarcoma could

be found, and the patient had an uneventful recovery. She left the hospital in five days and all wounds were healed in forty-five days.

Tissue examination was done and the pathologist Dr J M Hill reported (1) hyperplasia of submucosal lymphoid tissue in

Fig 1 (case 1)—Lymphosarcoma of the rectum. Section shows lymphoid tissue below the mucous membrane of the internal hemorrhoidal zone.

be found and it was agreed that the tumor was primary in the rectum. A series of twenty-four roentgen treatments were then given by Dr Carlson over a period of twenty-four days.

The convalescence was uneventful except for mild radiation sickness. All wounds were healed in forty-five days.

The patient was seen at monthly intervals for one year and twice in the last six months. Inspection and anorectal endoscopy were negative for recurrence at each examination.

The inguinal lymphatics were negative at the onset and have remained so to date.

CASE 2—Mrs D B, aged 36, was seen in consultation on May 6, 1941 for pain in the rectum, protrusion from the rectum and blood streaks on the toilet tissue following defecation. The symptom of protrusion was noticed from two to three months before consultation, however, the patient stated that she had been "constipated" all her life. Pain following defecation of moderate severity and streaking of blood on the toilet tissue had been noticed for two months. Anorectal inspection, palpation and endoscopy revealed (1) an ulcer in the posterior part of the anal region with hypertrophic anal papilla and (2) second degree internal hemorrhoids with thrombosis in the right posterior internal hemorrhoid.

Hemorrhoidectomy, anal ulcerectomy and papillectomy were done one week later, on May 13, at Baylor University Hos-

Fig 2 (case 1)—Lymphoma of the rectum. Lymphoid tissue is devoid of germinal centers and lymphoblasts predominate.

pital, and the patient had an uneventful recovery. She left the hospital in five days and all wounds were healed in forty-five days.

Tissue examination was done and the pathologist Dr J M Hill reported (1) hyperplasia of submucosal lymphoid tissue in

Fig 3 (case 2)—Lymphoma of the rectum. Section shows benign hyperplasia of the lymphoid tissue. Germinal centers are present.

CASE 3—Mr P C, aged 21, was seen in December 1940 because of rectal bleeding and protrusions. Both symptoms had been present for six months and the bleeding was at this time intermittent and not as great in amount as it had been in the beginning. The bleeding was always bright red. Anorectal examination revealed second degree internal hemorrhoids with thrombosis in the left lateral hemorrhoid.

Owing to the fact that the patient was a college student it was suggested that he wait until the summer recess of 1941 to have a hemorrhoidectomy.

Hemorrhoidectomy was performed on June 6, 1941 at Baylor University Hospital, and the tissue was sent for pathologic examination in compliance with the hospital's routine.

The pathologist reported hemorrhoids and hyperplasia of submucosal lymphoid tissue in the wall of the rectum (fig 4). Hospitalization lasted five days, and the wounds were healed in thirty days.

Follow-up examinations were done at three month intervals for almost a year without evidence of recurrence of a lymphoid tumor.

COMMENT

Roentgen therapy was not given in the last 2 cases since the tumors were benign and tissue healing in both was normal, with no tendency toward recurrence.

It is interesting that each case was clinically diagnosed as hemorrhoids because there were no other changes visible or palpable to stimulate one to think of any other lesion. While it is true that induration

Fig 4 (case 3)—Lymphoma of the rectum. Benign hyperplasia is shown in the germinal center of the internal hemorrhoidal zone below the mucous membrane.

to palpation was present, the zones were freely movable by the examining finger, and on endoscopy the maroonish purple look of internal hemorrhoids was present and, in fact, hemorrhoids were present in each case as proved by microscopic examination.

In an analysis of the 3 cases it will be noted that in each there was one hemorrhoidal zone with enough induration to provoke thinking of thrombosis in the internal hemorrhoidal zone. Thrombosis is occasionally seen in one or more of the three cardinal hemorrhoidal areas and is the usual cause of induration to the palpating finger in that zone.

From these cases it would seem necessary to remember that, while thrombosis is the usual cause of induration in the internal hemorrhoidal zones, all indurated internal hemorrhoids should be saved for microscopic examination of the tissue.

The primary purpose of reporting these cases was to make an appeal for histopathologic examination of all excised anorectal tissue, since all of these cases were diagnosed correctly from tissue study when the clinical preoperative diagnosis did not allow for the lymphoid changes present.

Correct tissue diagnosis of lymphosarcoma in case 1 led to early roentgen therapy and will deserve credit for the patient's life if she continues to live and not have lymphosarcomatous recurrence. Had this specimen been thrown away it is possible that without the aid of roentgen therapy she probably would not have had the close follow-up examinations and the process might have become extensive before she presented herself again.

In the other 2 cases correct tissue diagnosis has put all on guard and check-up examinations will be made at regular intervals with the use of roentgen therapy immediately should either or both show lymphoid tissue regeneration.

SUMMARY AND CONCLUSIONS

1 Because no cases of primary rectal lymphoid tumors resembling internal hemorrhoids could be found in the literature 3 such cases are here reported.

2 All surgically removed anorectal tissue regardless of the clinical diagnosis should be studied microscopically.

3 Early, sufficient roentgen therapy was given a patient with primary rectal lymphosarcoma of the anal canal following surgical excision, and clinically good results were proved by the test of time for one and one half years.

ABSTRACT OF DISCUSSION

DR CURTIS ROSSER, Dallas, Texas: This paper emphasizes particularly the constant necessity for careful microscopic examination of all tissue removed from the anorectum. Proctologists are in accord concerning the possibility of malignant degeneration or tuberculosis in inflammatory processes such as fistulas and ulcers. The possibility of specific tissue reaction in connection with hemorrhoids is not so well understood, however, and in some institutions there is a tendency to object to the routine examination of removed hemorrhoidal tissue. Dr Hirschman has reported the discovery of a colloid carcinoma in an internal hemorrhoid and I have reported 4 instances of malignant degeneration of hemorrhoidal tissue. Dr Smith's cases concern lymphoid deposits in the hemorrhoidal zone which require careful microscopic study to differentiate them from internal hemorrhoids. The various malignant and benign lymphoid tumors found in the rectum are remarkable primarily because of the variation in gross structure and appearance which means that the cooperation of the pathologist is always an essential in the final diagnosis. There is no agreement at this time as to the proper management of lymphoid intestinal tumors. Apparently, however, irradiation is advisable if the cells appear to be radio sensitive; otherwise surgical removal is probably indicated.

DR SIMON B. KATZNER, New Haven, Conn.: I want to add another case of lymphosarcoma of anal origin which was reported by me at the American Proctologic Society in 1938. No doubt the reason Dr. Smith didn't find this in the literature is that at the time I reported my case I emphasized the fact that it had to be differentiated from lymphogranuloma venereum because of the stricture and overgrowth of tissue around the anus and also because the patient was a Negro. The man had been referred to me after he had had a hemorrhoidectomy. Pathologic examination showed lymphosarcoma but on account of the other factors I continued further studies on him at the rectal clinic of the Yale Medical School. There we made Frey tests which were negative and we did a biopsy of the inguinal nodes which showed lymphosarcoma. He was referred to our tumor clinic and was given roentgen therapy. He did well and continued his work as a laborer but died about four years later of pneumonia. The question of lymphosarcoma not of the anal region but of the rectum is presented by Bensaude in a paper which he published about fifteen years ago. He reported about 20 cases and showed some beautiful color plates, however, as Dr. Smith brought out these cases were not lymphosarcoma of the anal region but lymphosarcoma of the rectum.

DR CLAUDE C. TUCKER, Wichita, Kan. In 1938 Dr C. A. Hellwig and I presented a paper before this section entitled "Proctologic Tumors," which was published in *THE JOURNAL*. At that time we laid emphasis on the pathologic examination of all tissue removed at the time of the operation. For the past twelve years we have sent all our tissues to the laboratory. We stated that many of the malignant tumors in our material were small and that 18 of the 52 malignant tumors were discovered during routine microscopic examination of what seemed clinically harmless lesions. In 6 of the malignant cases, cancer developed in previously existing anal lesions: 1 adenocarcinoma in a fistulous tract, 1 squamous cell carcinoma in a fissure, 3 adenocarcinomas in hemorrhoids and 1 basal cell carcinoma in external hemorrhoids. Since the publication of our paper we have had 3 cases of lymphosarcoma of the rectum which had their origin in the anal canal and were not suspected of malignancy. I feel that all tissue surgically removed should be reexamined.

CAPT. TOM E. SMITH, M. C., U. S. I have read Dr Kleiner's article in the 1938 Transactions of the American Proctologic Society and, if my memory serves me correctly, he did not refer to his case of lymphosarcoma as resembling an internal hemorrhoid. I have found no record in the literature of a cancer such as that reported here looking exactly like a benign lesion. There are numerous cases of rectal lymphosarcoma reported which were found by proctoscopic examination and digital palpation, but these stimulated thinking of malignancy. I wish to make a plea that anorectal tissue be sent to the pathologist even though on the surface it looks as though it should be thrown away.

THE TREATMENT OF EXPERIMENTAL SHOCK FROM REPEATED HEMORRHAGE

A PRELIMINARY REPORT ON THE USE OF PURE AMINO ACIDS AND OF HYDROLYZED PROTEIN

ROBERT ELMAN, M.D.

AND

CARL E. LISCHER, M.D.

ST. LOUIS

The amino acids of hydrolyzed protein have been shown in previous studies¹ from this laboratory and clinic to be effective in promoting the synthesis of serum albumin and in various types of hypoproteinemia. Nearly all of these were instances of chronic or subacute hypoproteinemia, many of nutritional origin. In this preliminary report we present experimental evidence that the same mixture of amino acids and polypeptides is beneficial in the therapy of acute protein loss which occurs in severe uncompensated (i. e. fatal) hemorrhage. Although the value of plasma and whole blood transfusions is an established principle of vast importance in the treatment of shock, it is probable that in wartime the number requiring such treatment might well exceed the available supplies of plasma and that in the armed forces many situations might arise in which blood donors were not available. Because of the relative ease and economy with which amino acid solutions can be made, stored, transported and given intravenously, they possess obvious practical advantages.

In experiments to be described in detail at a later date, we have found that dogs (in groups of 10) sub-

jected to repeated hemorrhage (10 cc per kilogram every hour) show a fairly constant drop in blood pressure, many of the symptoms of shock seen in man, and a fatal outcome on the average of 37 hours following the beginning of the experiment. This course of events was not changed when the removed blood was replaced immediately with 10 per cent dextrose in saline solution. However, when the replacement fluid consisted of a solution containing 5 per cent hydrolyzed protein and 5 per cent dextrose, the beneficial effect was quite evident and significant. In the first place, the blood pressure was maintained at a higher level, secondly, the mean survival was over five hours or nearly 50 per cent longer, and finally the amount of blood which could be removed before death was 25 per cent greater than in the controls. The magnitude of the effect was as great as that achieved with citrated plasma. Two hydrolyzed protein solutions² were used, both enzymatically digested, one from beef plasma, the other from casein (Amigen), the same beneficial effect was noted with each. However when a mixture containing all of the essential amino acids (as pure crystals) was used³ the beneficial effect, while definite, was not as pronounced as in the case of the hydrolyzed protein. This may have been due either to known differences in amino acid composition or to the fact that the larger aggregates of amino acids (polypeptides) which comprised 30 per cent of the protein hydrolysates are more beneficial than simple amino acids. The amount of nitrogen present was the same in the two solutions.

Caution must be expressed before applying the encouraging results of these experiments to the clinical treatment of surgical shock from hemorrhage. In the first place the present experiments, while satisfactory for the study of fatal shock due to uncomplicated loss of blood, differ in many respects from the conditions occurring in patients. Moreover, the method of fluid administration was much more rapid than the usual slow intravenous injections used clinically. In the second place the physiologic and biochemical mechanisms involved require much further investigation. We suspect, however, from a few observations, that the introduced amino acids and polypeptides are effective because they enable the liver to synthesize protein more rapidly, thus providing an added source of albumin from which to supply that lost in subsequent bleedings.

Nevertheless further study seems justified because the practical advantages of solutions of hydrolyzed protein should make it a welcome alternative for, or a supplement to, plasma transfusions. Thus the injection of 1 liter of plasma will always require bleeding four donors and considerable processing, whereas solutions of amino acids and polypeptides are as convenient to give as dextrose and saline solution.

SUMMARY

In fatal surgical shock experimentally produced by repeated hemorrhage, immediate replacement with a solution of hydrolyzed protein containing amino acids and polypeptides exerted a definite therapeutic effect as shown by prolongation of the survival time, an increase in the amount of hemorrhage which could be sustained and a higher level of blood pressure as compared with the controls, in which dextrose alone was used or in which there was no replacement. A solution containing pure crystalline amino acids exerted a similar but less pronounced effect.

EFFECT OF DIETHYLSTILBESTROL ON
NEUROLOGIC SYMPTOMS OF CAR-
CINOMA OF PROSTATE

BURDICK G CLARKE, MD

AND

HENRY R VIETS, MD

BOSTON

The rapid reduction of obstruction of the urethra by carcinomatous tissue in the prostate gland, when patients are treated by the estrogen diethylstilbestrol,¹ as reported by Kahle and Maltry,² Herbst,³ Kahle, Ogden and Getzoff,⁴ Heckel and Kretschmer,⁵ Wishard⁶ and Chute and Willets,⁷ has led to an investigation of a similar "unblocking" phenomenon in the release of cerebrospinal fluid when obstructed by metastases secondary to prostatic carcinoma. Metastatic lesions in the lumbosacral spine, causing pain in the legs from direct pressure on nerve roots or invasion of the spinal canal causing blockage of the cerebrospinal fluid and traction on the roots, are commonly discovered on roentgen examination and lumbar puncture in patients with prostatic cancer. The relief of these symptoms may be of more urgent concern than the urinary dysfunction, and thus the patient's chief complaint is "neuritis" or "rheumatism" rather than urinary retention. The history of a case of this type is here set forth, with notes on the rapid amelioration of the symptoms following the use of diethylstilbestrol.

REPORT OF CASE

History—W C F K, a married man aged 69, American, a carpenter who had worked at his trade until six weeks before admission, was admitted to the Neurological Service of the Massachusetts General Hospital May 5, 1942 because of difficulty in walking and pain in his legs of six to eight weeks' duration. The pain, which did not have segmental distribution, was intensified by walking, coughing or straining. There were no symptoms of prostatic obstruction.

Physical Examination—The patient was well developed. He could not move about briskly in bed because of pain in his legs and back. When asked to walk, he did so with a slow, deliberate gait. In all acts he guarded the lumbar spine, in which no motion appeared. There was tenderness over the spinous processes of the first three lumbar vertebrae. Coughing, straining, flexion of the head on the chest or of the thighs on the abdomen all accentuated the pain, suggesting that it might be due to a process involving the nerve roots in the lumbar region. The knee jerks and ankle jerks were not obtained, but no sensory changes, paralysis or atrophy were noted.

By rectal examination a hard, enlarged prostate gland was palpated. The tone of the rectal sphincter was normal. Roentgen examination showed osteoplastic metastases involving the first three lumbar vertebrae. A study of the cerebrospinal fluid pressures and dynamics showed almost complete "block" of the spinal canal between needles inserted between the twelfth

thoracic and first lumbar and the fifth lumbar and sacrum. The fluid obtained from the second locus was yellow, with a protein content of 798 mg per hundred cubic centimeters. Atypical cells, thought by the pathologist to be malignant were aspirated from the epidural space between the third and fourth lumbar vertebrae.

Laboratory Reports—The serum acid phosphatase was 4.4 and 4.5 Gutman units on two determinations the upper limits of normal being regarded as 4. Serum alkaline phosphatase was 7.8 Bodansky units the normal range being considered as 3 to 5. The serum phosphorus was 3.9 and 4 mg per hundred cubic centimeters on two determinations. The daily urinary excretion of 17-ketosteroids was on two occasions estimated as 10.4 and 7.3 mg within the normal amount for elderly men without prostatic disease. The red blood cell count was 5,250,000 per cubic millimeter of blood and the hemoglobin 14.4 Gm per hundred cubic centimeters (Sahli). The white blood cell count, the differential count and the urine were within the limits of normal and the Hinton test on the blood and the Wassermann test on the cerebrospinal fluid were negative.

Treatment—A course of twelve intramuscular injections of 10 mg daily of diethylstilbestrol in oil was begun sixteen days after admission. The patient felt better within twelve hours, was walking about the ward without pain in four days and regarded himself as well eight days after treatment was started. Twelve days after his first treatment the dynamics of the cerebrospinal fluid were normal and the protein was greatly

reduced in amount. He was discharged from the hospital on the thirteenth day of treatment with orders to take diethylstilbestrol 6 mg daily by mouth.

Subsequent Course—Three weeks after discharge, while he was still taking 6 mg of diethylstilbestrol daily, firm pitting edema of the lower legs and ankles developed. On examination it was noted that both testes had become atrophic and some hypertrophy and tenderness of subcutaneous breast tissue had developed. The dosage of diethylstilbestrol was reduced to 3 mg a day, by mouth and the patient, free of pain, returned to his work.

On August 6, seventy-seven days after the treatment was started, he was readmitted to the hospital for study having received a total of 120 mg of diethylstilbestrol intramuscularly and 231 mg orally. He felt well and had a good appetite, and his weight had increased from 158 to 162 pounds (71.7 to 73.5 Kg). He reported that he could do twice as much work as his 40 year old partner. No personality changes were noted. He had lost his libido. The prostate gland had become soft, smooth and half its previous size. Edema of the ankles and mild gynecomastia persisted. Knee jerks and ankle jerks were now easily obtained. There was no tenderness or guarding of the lumbar spine on walking or pain on coughing or on flexion of the neck or thighs. Lumbar puncture showed complete disappearance of the cerebrospinal fluid "block," with the protein values at the twelfth thoracic and first lumbar and the fifth lumbar and sacrum not significantly elevated (as shown in the accompanying table).

The urinary output of 17-ketosteroids had dropped to 2.2 mg a day, the serum acid phosphatase was 6.4 Gutman units, alkaline phosphatase 6.2 Bodansky units and serum phosphorus 3.2 mg per hundred cubic centimeters. The urine white blood cell count and differential count remained normal but the

red blood cell count had dropped to 3,780,000 per cubic millimeter of blood and the hemoglobin to 11.9 Gm per hundred cubic centimeters (Sahli).

Röntgen examination showed no definite change in the metastases in the lumbar vertebrae. A study of a specimen obtained from a needle biopsy of the prostate gland disclosed malignant tissue, although comparative histologic evidence of regressive changes under treatment could not be definitely established, since the needle biopsy before treatment had failed to yield prostatic tissue.

The patient continued to take diethylstilbestrol by mouth for seventy-seven days, remaining free from symptoms during this period. Three months later, however, symptoms returned with pain in the lumbar region and in the legs, made worse by coughing or sneezing. His gait became unsteady and weak. On examination Dec. 4, 1942 the condition was not dissimilar to that found previous to diethylstilbestrol treatment. The cerebrospinal fluid "block," however, was even more pronounced than it had been before, the total protein in the lower needle being 750 mg per hundred cubic centimeters. Bilateral orchiectomy was done and in five days the patient was completely relieved of his symptoms. An examination of the cerebrospinal fluid two weeks after operation showed that the "block" had completely disappeared, the total protein being 80 mg per hundred cubic centimeters.

A subsequent note giving more details of the later treatment of this patient will be forthcoming. In the meantime we may contrast the rapidity and completeness of the relief of the cerebrospinal fluid block by diethylstilbestrol and by operation. The operation of bilateral orchiectomy appears to have removed a more severe block in quicker time than the treatment with diethylstilbestrol.

COMMENT

Adult prostatic epithelium, whether normal, hyperplastic or malignant, is known to undergo regression of activity and atrophy when the androgenic substances are greatly reduced in amount, either by castration or by inactivation through the administration of estrogens such as diethylstilbestrol.⁸ Kahle and Maltry⁹ treated 14 patients with prostatic hyperplasia with diethylstilbestrol and noted a consistent decrease in the size of the gland. Similar results in a series of cases of carcinoma of the prostate are reported by Kahle, Ogden and Getzoff,⁴ whose patients were also examined for histologic evidence of regressive changes by Schenken, Burns and Kahle.⁸ Comparative changes have also been shown by Heckel and Kretschmer.⁵ Chute and Willets⁷ give the actual measurements, by the use of proctocystograms, of the prostate gland before and after treatment with diethylstilbestrol, showing a reduction in size.

In addition to the reduction in size of the gland, the secondary lesions of bone metastases are also affected. Huggins, Stevens and Hodges⁶ demonstrated by serial roentgenograms increased density of bone metastases in patients under treatment by castration. Kahle, Ogden and Getzoff⁴ observed less consistent changes in serial roentgenograms as well as definite regression of lymph node metastases in 2 patients treated with diethylstilbestrol.

That the serum acid phosphatase level is usually elevated in carcinoma of the prostate with metastases has been shown by Robinson and the Gutmans⁹ as well

as by Herger and Sauer.¹⁰ Huggins and Hodges¹¹ observed a sharp decrease in serum acid phosphatase in 5 patients treated with estrogens as well as in 6 out of 8 patients after orchiectomy. In 3 patients given injections of the androgen testosterone dipropionate after orchiectomy, pain recurred and the serum acid phosphatase levels rose. In our case, contrary to the usual findings, the serum acid phosphatase increased after treatment from 4.4 to 6.4 Gutman units.

Satterthwaite, Hill and Pickard,¹² who have treated 10 patients by castration, with relief of symptoms, have noted that the urinary output of 17-ketosteroids in patients suffering from prostatic carcinoma, with or without metastases, is within normal limits for elderly men but falls significantly after operation, as it did in our case after treatment with diethylstilbestrol.

A number of side effects have been reported in the treatment of cancer of the prostate with diethylstilbestrol, or by castration, which include hypertrophy of breast tissue, testicular atrophy and the loss of libido and the power of ejaculation. In patients treated by castration loss of sexual capacity, hot flashes and temporary edema of the ankles have also been observed.

Possibly of significance is a reduction in the number of red blood corpuscles and the amount of hemoglobin in the blood. Our patient showed a decrease from 5,250,000 red blood corpuscles per cubic millimeter to 3,780,000 per cubic millimeter and a loss of hemoglobin from 14.4 Gm per hundred cubic centimeters to 11.9 Gm per hundred cubic centimeters. No definite statement can be made at the present time as to whether this change resulted from the carcinoma itself or from the treatment.

Before diethylstilbestrol was used, in the case reported there was almost a complete "block" in the cerebrospinal fluid between the two needles inserted in the lumbar spine at the levels below the twelfth thoracic vertebra and the fifth lumbar vertebra. The fluid showed the characteristics of From's syndrome, with a yellow color, a total protein content of 798 mg per hundred cubic centimeters and a partial response to rise after jugular compression in the lower needle. Subsequent to the taking of diethylstilbestrol by injection and by mouth, the cerebrospinal fluid "block" disappeared, as shown by the establishment of normal color, the return of the dynamics on jugular compression to normal and the reduction of the protein to 52 mg per hundred cubic centimeters. The evidence is clear that the treatment with diethylstilbestrol actually reduced the compressing element in the spinal canal which acted particularly as a means of blocking the pathway of the cerebrospinal fluid. The use of this estrogenic substance, therefore, served to release the "block," and presumably this was the principal factor in relieving the symptoms of pain and difficulty in walking. Prior to treatment the patient was worse in the upright position or when coughing or straining. Subsequently none of these maneuvers caused pain. After leaving the hospital, the patient was able to carry on a usual day's work as a carpenter without a recurrence of his symptoms.

Huggins, Stevens and Hodges⁸ reported a case, with similar symptoms to ours, responding favorably to orchietomy. A man aged 71 had abdominal and low back pain, numbness over the buttocks and posterior part of the thighs as well as urinary and fecal incontinence. The deep reflexes in the legs were absent. The cerebrospinal fluid was yellow with an increase in protein content. Roentgen rays disclosed extensive osteoplastic metastases. Within three days after bilateral orchietomy, the patient was relieved of pain and in seven weeks continence was restored, a decubitus had healed and the cerebrospinal fluid had become clear. Details of the fluid are not given, but the evidence points to a release of "block," as in our case, by orchietomy, without the use of diethylstilbestrol.

CONCLUSIONS

A patient with carcinomatous metastases from the prostate causing a "block" in the pathway of the cerebrospinal fluid and pain from pressure or traction on the spinal nerve roots was relieved by treatment with diethylstilbestrol. The response was rapid and remarkably complete. The release of the "block" was demonstrated by serial lumbar punctures at appropriate levels, as well as by the relief of pain and the return of the knee jerks and ankle jerks.

Massachusetts General Hospital

THE EFFECTS OF ASCORBIC ACID IN RELATION TO LEAD ABSORPTION

E E EVANS, MD

W D NORWOOD, MD

DEEPWATER, N J

R A KEHOE, MD

AND

WILLARD MACHLE, MD

CINCINNATI

The experimental observations described in the following paragraphs were prompted by the reports of Holmes and his associates¹ on the beneficial effects of the administration of ascorbic acid to persons suffering from chronic lead poisoning. These investigators noted a decided reduction in the symptoms of exposed workmen and an apparent decrease in the lead content of the blood and the urine following the daily ingestion of ascorbic acid. This was associated with an increase in the number of erythrocytes, a decrease in the number of stippled erythrocytes and an increase in the hemoglobin content of the blood. They inferred that ascorbic acid combined with lead to form a relatively insoluble or unionized compound that might be eliminated through the bile into the feces.

The importance of these conclusions from a practical point of view, stimulated our efforts to verify them. If they proved to be true in our hands, it would be feasible to supply the necessary ascorbic acid in convenient form as a prophylactic measure, in addition to the procedures concerned with the control of the lead exposure.

While our work was in progress, other experimental studies, as well as case reports, have appeared in evi-

dence of widespread interest in this subject. Dannenberg, Wideman and Friedman² have described an unsuccessful attempt to treat a case of lead poisoning with ascorbic acid. Pillemer and his colleagues³ have reported that animals poisoned with lead do not respond favorably to ascorbic acid therapy. However these investigators as well as Betti⁴ carried out experiments on animals the results of which clearly indicate that ascorbic acid protects animals against the toxic effects of lead absorption although it is not quite clear whether any specific benefit is conferred beyond that incident to the prevention of a deficiency of the vitamin. Marchmont-Robinson⁵ has reported his observations on a group of workmen exposed to lead and has concluded that the administration of ascorbic acid is beneficial in terms of reduction of toxic symptoms but that it is without significant effect on the urinary lead excretion. Neither conclusion appears to have been fully substantiated by adequate control data.

METHODS OF STUDY

Selection and Classification of Exposed Workmen—An ideal group of four hundred men was available for study in a plant for the manufacture of tetraethyl lead. Since this organic lead compound is dangerously volatile at ordinary temperatures and is also susceptible of absorption through the skin, every precaution is taken to control the manufacturing processes against leakage or escaping vapor. In addition, general and locally applied ventilation is employed to maintain the lead concentration in the air within safe limits.

At intervals of three weeks, each man receives a special examination, the nature of which is indicated by the accompanying record form. Laboratory work includes a determination of the hemoglobin by the Haden-Hausser method at each examination. At every fourth examination (twelve week intervals) a complete blood study is made including enumeration of the erythrocytes, stippled erythrocytes and leukocytes, a differential leukocyte count and a determination of the hemoglobin. At this time also a clinical analysis is made. If any suggestive signs or symptoms exist, specimens of urine, feces or blood or all three are sent to the Kettering Laboratory of Applied Physiology (University of Cincinnati College of Medicine) for determination of the lead content. When suggestive evidence of early toxic effects exists, the man's work is changed. By early toxic effects we do not mean lead colic, neuritis or encephalitis but rather unexplained fatigue, headache, slight loss of weight, insomnia, indigestion, constipation, anorexia, mental excitement, dreams, hemoglobin under 75 per cent, red count under 4,200,000 or increase in numbers of stippled erythrocytes. Frequently a change in diastolic blood pressure to 60 or lower which persists from week to week is the earliest physiologic sign of toxic effect.

In addition to the special examination, each man receives annually a complete physical examination, which includes a roentgenogram of the chest.

As an additional check on the lead exposure, a group of seventy-two representative workmen is studied

From the Medical Department of the Dye Works, E. I. DuPont de Nemours & Co. (Drs. Evans and Norwood) and the Kettering Laboratory of Applied Physiology, University of Cincinnati College of Medicine.

⁵ Marchmont-Robinson, S. W. Effect of Vitamin C on Workers Exposed to Lead Dust. *J. Lab. & Clin. Med.* **26**: 1478-1481 (June) 1941.

On a large sheet, every complaint and every illness resulting in loss of time during the year, together with the length of time lost were listed for each man. The results of quarterly urine and fecal lead analyses were listed for the year of the experiment and for the previous year when neither group was receiving ascorbic acid. Lead analyses on the blood of the men, carried out before and during the administration of ascorbic acid to the test group, were tabulated on the same sheet. All abnormal urinary findings were noted. All leukocyte counts above 10,000 and all erythrocyte counts below 4,300,000 were recorded, as were hemoglobin determinations below 75 per cent and stippled erythrocyte counts in excess of 10 per hundred thousand (fifty fields).

During the past few years, workers at the Haskell Laboratory of Industrial Toxicology in Wilmington, Del., under the direction of Dr. John H. Foulger, have made extensive studies of blood pressure and pulse changes. In brief, they have found that diastolic blood pressure readings greater than 93 or less than 65, pulse

pressure greater than 58 or less than 30 and pulse rates greater than 89 or less than 61 are definitely abnormal. All circulatory abnormalities fitting these criteria and occurring during the year among the men of the two groups were tabulated on the large sheets.

EXPERIMENTAL RESULTS

The large charts of assembled data are not shown for lack of space, but a series of smaller tables present the essential data and compare the thirty-six men taking ascorbic acid to the thirty-six controls with respect to the excretion of lead in urine and feces, the concentration of lead in the whole blood, the microscopic blood findings, the circulatory abnormalities and the early complaints that may conceivably be related to mild toxic effects of lead absorption.

Table 2 shows the results of the analyses of the blood. The data on both groups, as presented here, apply only to persons on whom results were obtained both in 1939 and in 1940. A scattering of unpaired figures resulting from failure to obtain blood samples at the right time and from the loss of a few samples in transit had to be discarded. There is only one set of results that shows any noteworthy divergence from the others

From the statistical point of view this difference between the mean value for the test group during the period of administration of ascorbic acid and that for any of the other sets of results is not quite four times its own probable error and is not certainly significant. In physiologic terms the difference is so slight as to be

of little or no consequence regardless of its statistical interpretation. If any doubt could be entertained on this score, it would be dispelled by the data on the urinary lead concentration as recorded in tables 3 and 4. Previous experience has demonstrated clearly that changes in the availability of lead within the body have a proportionally greater effect on the urinary lead concentration than on the lead concentration in the blood.

The results obtained on the samples of urine were first listed for the individual quarters in which the samples were obtained. The dates of sampling were the same for the test and the control group and were also approximately the same for the two years repre-

sented. The distribution of the results was generally similar for the respective quarters throughout the years, and therefore, for purposes of comparison, they were combined for each year, as seen in tables 3 and 4. Samples were lacking for some of the individual subjects during one or more quarters in 1939, and therefore there was a smaller total number of results for 1939

There is no reason for supposing that this fact could influence the general spread or any other characteristic of the data as a whole. It is obvious that no significant change occurred in the urinary lead concentration either as between the control and test group or between the years 1939 and 1940.

Any differences which might occur in the fecal lead content or concentration from quarter to quarter, from year to year or from one group to another would have to be interpreted with great caution in view of the overwhelming predominance of ingested lead over excreted lead in determining the extent of the fecal lead elimination. Nevertheless the fecal results expressed in terms of the quantity of lead per gram of fecal ash have been tabulated in tables 5 and 6. The most cursory examination of the results demonstrates the similarity of the groups throughout the period involved in this respect.

Table 7 gives the pertinent clinical data and the general findings of the clinical laboratory for the two groups. No significant difference can be seen in the numbers of erythrocytes or of stippled erythrocytes, or in the hemoglobin content of the blood. Likewise the number of abnormal circulatory findings was approximately the same in the two groups. There was little difference in the number or severity of the complaints that could be referred to possible lead effects. These

complaints were grouped under the main headings of gastroenteric tract symptoms, constipation, headache, nervousness, fatigue and rheumatic pains. The gain in weight differed insignificantly. It was surprising to find no difference in the two groups in the matter of symptoms, since in checking the men who took ascorbic acid, twenty-one of the thirty-six, or 58 per cent, reported some improvement such as less fatigue, more regular bowel movements, improvement in appetite and sleeping. However, verbal reports were similar in a large group of lead workers being given all the vitamins except ascorbic acid. As may be seen from table 7, there were more of the ascorbic acid group who lost time due to sickness than in the control group, and the total time lost was greater.

CONCLUSIONS

Ascorbic acid nutrition in workers in a large plant was found to be generally poor and somewhat poorer in lead workers than in others.

TABLE 7—Clinical Findings on 36 Men Taking 100 Grams of Ascorbic Acid Daily for a Year Compared with Clinical Findings on 36 Men Not Taking Ascorbic Acid

	Group Taking Ascorbic Acid		Control Group	
	Number	Per Cent	Number	Per Cent
Abnormal blood pressure	20	56	2	6
Abnormal pulse pressure	10	28	8	22

Low hemoglobin	10	28	8	22
High count of stippled erythrocytes	11	31	11	31
Weight increase	20	56	10	28
Net average gain in pounds	16		0.5	
Gastroenteric complaints	1	3	1	3
Constipation	12	33	13	36
Headache	0	0	11	31
Nervous complaint		8	0	0
Fatigue and rheumatic pain	1	3	7	19
Lost time illness	15	42	17	47
Lost time	4 days		6 days	

Careful study of a large group of lead workers failed to reveal any effect of ascorbic acid taken orally in daily quantities of 100 mg. on the lead concentration in the blood or on the elimination of lead in the feces or urine.

No difference was noted in the physical condition of the men or in the number and severity of complaints. No change was found in the numbers of erythrocytes or stippled erythrocytes or in the hemoglobin in the blood.

No reason has been found for recommending the use of ascorbic acid to minimize the effects of lead absorption.

The Movement Westward—When our forefathers were sick they freed the necessity not only of overcoming their diseases virtually unaided but also of withstanding the treatment that was designed to cure them. Only the sturdy survived. Those who lived to carry on the race possessed a physical fiber that was both tough and resilient—a constitutional endowment that they needed when the movement westward began. Although historians tell us that the pioneers climbed mountains, waded through swamps, swam rivers, endured extremes of heat and cold, suffered from thirst and hunger on the plains and fought the hostile Indians because of the lure of gold or the promise of new and more fertile lands, it is also possible that they left the East to escape their doctors.—Irving Frederic C. Safe Deliverance, Boston, Houghton Mifflin Company, 1942.

Clinical Notes, Suggestions and New Instruments

TREATMENT OF EPILEPTIFORM ATTACKS CAUSED BY CALCIFIED ADRENALS

WILLIAM LINTZ M.D. BROOKLYN

History—I P S F, a boy aged 11 years, when seen in 1937, gave the history of having suffered from epilepsy since he was 2½ years old. The convulsions first came on shortly after an ordinary attack of measles suffered at that time. For a few years they were very frequent but gradually diminished in number until they averaged only two to three attacks a month. These convulsions were not preceded by an aura. An upset stomach or an oral temperature of 100 F or more, from whatever cause, was very sure to bring on an attack. No individual article of diet condition of the bowels or nervous strain was responsible for these convulsions. They began spontaneously, like lightning from a clear blue sky, apparently without cause, as on one occasion when after spending a prolonged afternoon at the movies, he ran a block to his car only to be seized by a violent convulsion in front of it.

These convulsions did not begin in any special part of the body. They were general, with practically every muscle participating. They were clonic in character, lasting from one to five minutes, during which time there was complete loss of consciousness. There was no foaming at the mouth and no biting of the tongue. There was no loss of strength of the sphincters. At the end of an attack the patient gradually regained consciousness without having the slightest recollection of the convulsion. He not infrequently vomited and felt 'lousy' for the rest of the day. The attack was not followed by confusion, drowsiness or sleep. These attacks occurred equally day and night and during his sleep.

The boy had a brilliant mind. At 11 he already had been graduated from elementary school. He was highly intelligent, possessed an unusual fund of knowledge and had an excellent memory. I found him good natured kind and lovable. He tired very easily and could not participate in strenuous games. When he was 3 or 4 years old it was impossible for him to walk ten blocks. Even at 11 he had to be in bed by 7 and certainly never later than 9 o'clock. His legs would give out. He petered out toward the end of a game. He had a tendency to constipation.

A tonsillectomy was performed and the patient had pneumonia at 1, an attack of measles was followed by an obscure illness and then by these convulsions at 2½ years of age. An appendectomy performed later on gave no relief from these attacks.

There was a definite history of allergy on the mother's side and of diabetes on the father's side.

Physical Examination—The boy weighed 89 pounds (40.4 Kg), was 58½ inches (149 cm) tall and had a blood pressure of 88 systolic and 75 diastolic. His body was covered with numerous supernumerary adrenal spots—those brown black

eliminated certain foods to which by cutaneous test and by history he was found to be allergic and substituted 3 to 4½ grains (0.2 to 0.3 Gm) of phenytoin sodium for the phenobarbital. His convulsions were unabated.

I next saw the patient two years later when he was 13 years of age and at the end of the second year in high school. As usual, he was at the head of his class.

In view of the utter lack with the exception of the convulsions, of all stigmas of long standing epilepsy—mental deterioration, aura, lingual injury and loss of sphincter control—and an absent family history of epilepsy, in spite of the previous diagnosis of epilepsy made by many colleagues of unusual reputation in this field, I decided to re-study the case.

I asked the patient to keep a diary and I was struck by the tremendous spontaneous intake of sweets—ice cream candy, sodas, puddings and honey.

Many blood examinations were made. Typical findings are as follows: Hemoglobin 75 per cent, red blood cells 3,770,000,

Arrows point to calcified adrenals. The previous atonic and redundant large intestine became normal after vitamin B therapy.

white blood cells 8,350, polymorphonuclear leukocytes 69 per cent, small lymphocytes 18 per cent, large lymphocytes and transitionals 10 per cent and eosinophils 3 per cent. Microcytes and poikilocytes were present. The results of the sugar tolerance test are given in the accompanying table.

The basal metabolic rate varied between minus 2 and minus 12. A gastric analysis, in which crackers and water were used gave negative results as the result of physical and chemical examination of 260 cc of stomach contents extracted after forty-five minutes. The feces were normal.

Examination—Fluoroscopy of the chest showed a very small heart—drop heart, otherwise everything was normal.

A gastrointestinal series of roentgenograms was completely negative. On previous investigations atony and redundancy of the large intestine had been found. I find that the administration of large doses of vitamin B restores such bowels to normal. Pancreatic studies proved negative.

These roentgenograms showed what was of paramount importance—complete calcification of both adrenal glands.

The peculiar sugar tolerance reaction and the completely calcified adrenals changed the entire aspect of the condition. For the first time there was a lucid and logical explanation

Results of Sugar Tolerance Test

Sugar tolerance test—100 Gm. of dextrose used	Urine Sugar
Fasting 85.7 mg. per 100 cc. of blood	Negative
1 hour 85.7 mg. per 100 cc. of blood	Negative
2 hours 85.7 mg. per 100 cc. of blood	Negative
3 hours 85.7 mg. per 100 cc. of blood	Negative
4 hours 85.7 mg. per 100 cc. of blood	Negative

spots from which Coopman was able to extract epinephrine. The blood count was normal and urinalysis gave negative results.

Treatment—In the past he had been on all sorts of diets and had been given all sorts of enemas and all his life he had been taking daily 2 grains (0.13 Gm) of phenobarbital. I placed him on a high calcium diet especially rich in vitamin B,

of all the symptoms. The diagnosis of epilepsy was abandoned. The obscure illness after the attack of measles which was followed by these attacks of convulsions was evidently caused by tuberculosis of both adrenal glands with their subsequent calcification. For tuberculosis to follow measles is by no means a rare occurrence.

While I was unable to do a blood sugar determination during a convulsion, it is evident from the sugar tolerance tests that he was unable to mobilize dextrose when he most needed it. That hypoglycemia will produce convulsions is too well known for discussion. In fact, it is the basis for treatment of certain mental diseases.

The disturbed physiology of the adrenals explains the patient's symptoms. If one bears in mind what epinephrine does, it is evident that all his symptoms are explained by his calcified adrenals.

Epinephrine stimulates the conversion of glycogen in the liver and possibly in the muscles, into dextrose which is then poured into the circulating blood. The level of the blood sugar rises, and if it exceeds the renal threshold some sugar will be excreted into the urine. If the liver has previously been emptied of the glycogen, it is stated that a rise in the blood sugar level may still result from epinephrine.

Epinephrine performs the following functions:

1 It aids the redistribution of the blood in the body and increases the force and rate of the heart. A large dose of epinephrine may cause the minute output of the heart to increase by 90 per cent, partly by an increase of rate and partly through an increased output per beat. It thus enables the heart to cope better with a larger venous return.

2 It mobilizes liver glycogen and provides sugar for the active tissues.

3 It diminishes fatigue in the skeletal muscles. This is an important action. The muscles work to better advantage because of the increased supply. It constricts the vessels of the skin, but the vessels supplying the skeletal muscles dilate. In addition, it has been stated that epinephrine increases the force of contraction both of normal and of fatigued muscles in response to stimulation through its motor nerve.

4 It possibly increases the red blood cell count and thus the oxygen carrying power of the blood by stimulating the smooth muscle of the capsule of the spleen, which discharges the red blood cells stored in the interstices of the pulp.

5 It brings about relaxation of the bronchi, facilitating ventilation of the alveoli.

6 It is responsible for dilatation of the pupils and closure of the sphincters.

What better treatment is there, next to the administration of dextrose intravenously, than a shot of epinephrine for the treatment of hypoglycemia? The liver is vitally concerned with the regulation of the normal level of the blood sugar. When the blood sugar rises it stores glycogen, and it is aided in this process by insulin. When the blood sugar falls it responds in two ways. 1 It mobilizes glycogen by converting it into dextrose. It is stimulated to act in this way by impulses reaching it from the sympathetic nervous system and by the epinephrine. 2 It forms new glycogen mainly from protein and is stimulated to do this by the diabetogenic hormone.

Since normally only 5 Gm of dextrose is present in the blood and since the sugar may be consumed suddenly and excessively, the mechanism of replacement must be very finely balanced. Yet in this patient it was grossly disturbed.

The adrenal cortex is essential to life, the medulla is not. If both adrenals are removed death results in from four to five days. Accessory cortical tissue must be present in order to survive.

I believe that the reason for the number of convulsions becoming smaller as he grew older is that he was developing accessory adrenals.

Treatment—This was simple and effective. Instead of relying on his liver as the storage place and warehouse for his sugar, he now carries in his pocket some form of dextrose to be taken at frequent intervals.

I do not believe that this is a patient to be treated with the usual high protein, high fat diet as a patient with hypoglycemia resulting from hyperinsulinism. This condition is entirely differ-

ent from such a hypoglycemia, in which by administering excessive amounts of dextrose one would further stimulate the secretion of insulin, thus increasing the hypoglycemia further by establishing this vicious cycle. He also takes adrenal cortex extract orally three times a day between meals.

REFLECTIONS

The boy is now a brilliant student in college. He is in perfect health. In the last three years he has had two attacks—one after playing football and the other following an all night fraternity spree. In both instances he omitted taking dextrose. Under the circumstances, both attacks could have been predicted and avoided. Recently he suffered from an attack of mushroom poisoning, which produced violent gastrointestinal symptoms but no convulsions.

I wonder whether Cæsar and Napoleon, who supposedly suffered from epilepsy, did not have a similar condition. They also possessed brilliancy instead of the mental deterioration common to epilepsy of long standing.

Epileptic patients should have made not only a sugar tolerance test but also studies of the pancreas and adrenal glands.

STATISTICS ON THE PATIENT LOAD OF PHYSICIANS IN PRIVATE PRACTICE

ANTONIO CIOCCO, MD

AND

ISIDORE ALTMAN

BETHESDA, MD

With the induction of thousands of physicians into the armed forces and the resulting changes in the density, distribution and composition of physician groups, the problem of determining precisely the number of physicians required for the civilian needs of an area and the number that could be shifted from one area to another or to the armed services has become more than ever important. Any such determination requires accurate knowledge about (a) the number of persons who will demand medical care, (b) the amount of medical care they will require and (c) the physicians' time necessary to supply the required service. Spe-

TABLE 1—District of Columbia Questionnaire

The physicians were asked to state:

		Office	
		Hospitals	
		Home visits	
		Hospital or public clinics	

cific knowledge on the three variables is unfortunately difficult to obtain. However, the integration of the three variables equals the number of patients seen by the physicians of an area in a given unit of time. Therefore, as a first approach toward a quantitative estimate of civilian needs for medical care, use can be made of data on the patient load carried by physicians. Such data have been collected for Washington, D. C., and the state of Maryland and constitute the basis of this report.

From the Division of Public Health Methods, National Institute of Health, U. S. Public Health Service. A study carried out for the Committee on the Allocation of Medical Personnel of the Procurement and Assignment Service.

MATERIAL AND METHOD

The data on the patient load of physicians are derived from successive studies which the Procurement and Assignment Service for Physicians, Dentists and Veterinarians made in the District of Columbia and in the state of Maryland¹ in 1942 primarily to obtain information about the number and proportion

TABLE 2—*Maryland Questionnaire*

of nonresident patients seen by the physicians of Washington D. C., and of the communities of Maryland. The studies were conducted by means of questionnaires sent to all the physicians in private practice.

The first of the studies covered the District of Columbia (table 1).

Within a week's time from the date on which the questionnaires were mailed 50 per cent of the physicians had replied and by the time the study was closed replies had been received from 60 per cent of the practitioners.

From a preliminary analysis of the responses it became apparent that within the week's span for which information was requested the number of visits or calls did not exceed by any substantial amount the number of "patients." What differences existed between "visits or calls" and "patients" usually arose from the amount of services rendered in hospitals. It was also apparent that the physicians were on the whole not in a position to describe the day's routine in terms of the hours of the clock generally spent in the office or hospital or at the homes of patients. A high proportion of them frankly admitted they could not give any definite information on the point, and others simply left the question unanswered.

In view of these observations the questionnaire was simplified in the succeeding inquiry made in Maryland (table 2).

Space for the physician's signature was left on the questionnaire and almost all the physicians duly signed the replies, generally adding helpful explanatory comments about their activities.

The number of physicians in private practice to whom the questionnaires were sent equaled 991 in the District of Columbia

and 1623 in Maryland. Replies were received from 597 or 60 per cent, of the practitioners of the District of Columbia and 1,065, or 66 per cent of the Maryland physicians.

The percentage of replies obtained from each age, sex and race group of the District of Columbia physicians is reported in table 3. It will be noted that among the white male practitioners replies were received from 64 per cent while less than 50 per cent of the Negro male and of the female practitioners answered. It may be that some of the last group identified the questionnaire with the procuring of physicians for the armed services and therefore assumed that a reply was not really desired.

When the white male physicians of the District of Columbia are classified according to type of practice into general practitioners and specialists (practice limited to a specialty as indicated in the records of the Medical Society of the District of Columbia) it is found that a slightly higher percentage of specialists than of general practitioners replied. The difference is particularly noticeable in the under 35 age group but it should not be forgotten that the numbers involved are small. On the whole it appears that the several age groups of physicians replied in equal proportion to their number.

A tabulation of the total number of Maryland physicians according to age, sex, color and specialty for October 1942 is not available. However a comparison can be made between the distribution of the several categories of physicians who replied and the distribution observed among those counted in a survey made in June 1942. Of the total physicians who replied 93 per cent were white males, 4 per cent Negro males and 3 per cent white females. In June the white males constituted 92 per cent of all practitioners and the Negroes and the females 5 and 3 per cent respectively. Among all the physicians enumerated in June 67 per cent practiced in Baltimore City and among the physicians who replied 65 per cent practiced in that city. In the count of Baltimore City physicians 56 per cent of the physicians were general practitioners. Of the replies to the

All ages	500	89	7	20	126	68	85

questionnaire, 51 per cent were from general practitioners. The percentage of white male practitioners equaled 43 in the June census, it equaled 40 among the physicians who replied to the questionnaire.

Other comparisons between the composition of the sample of physicians who cooperated in the study and of the total number

¹ Dr F. V. McGovern, chairman of the District of Columbia Procurement and Assignment Service, Mr Theodore Wiprud, executive secretary of the Medical Society of the District of Columbia and Dr C. W. Maxson, chairman of the Maryland Procurement and Assignment Service, cooperated in these studies.

enumerated four months previously also reveal only slight and insignificant differences. Therefore, it seems safe to conclude that both in the District of Columbia and in Maryland the physicians who replied to the questionnaire are on the whole fairly representative of the total physician population in the two areas, at least for the characteristics noted.

Chart 1—Patients seen in one week by white male general practitioners September-October 1942

Not all of the total 1,662 replies received have been utilized for the purposes of this study. The reasons for excluding some of the schedules are several. In the District of Columbia sample lack of internal consistency due to misunderstanding of the term "visits or calls" has been a relatively frequent cause for exclusion. In both samples the records of physicians who were absent from their practice all or part of the week have not been included. Furthermore, some of the physicians who routinely render service in clinics counted clinic load among the patients seen. Such records, when they could be identified, have also been discarded.

With reference to possible inaccuracies in the statements made by the physicians no check has been attempted, nor can any estimate be made at present of the amount or direction of any bias that may have been introduced in the replies.

WEEKLY PATIENT LOAD OF GENERAL PRACTITIONERS

In the group of general practitioners are included all the physicians except those whose practice is actually limited to a special field of medicine.

The distribution of the number of patients per physician and the average weekly patient load of the physicians of the four age groups considered are shown in charts 1 and 2 and table 4. With reference to the variation among physicians, chart 1 shows that the number of patients seen in a week may range from less than 40 to more than 300. The wide dispersion is emphasized by the values of the standard deviation. These values indicate that the total patient loads of two thirds of the general practitioners, when all ages are combined, vary between 30 and 200 patients weekly, and the office patient loads vary between 20 and 150 patients. This wide range probably reflects the many

varieties of activities of the general practitioner. Some services may require only a few minutes of attention while others may require several hours. Moreover, even among general practitioners there will be some whose services are preponderantly of a kind requiring either a low or a high expenditure of time per patient. It must not be forgotten either that notwithstanding special efforts to eliminate them from the computations, there may be included a few physicians whose patient load as stated contained clinic patients. It is pertinent in this respect to note that the range and standard deviation are nearly the same for practitioners of Baltimore City, Washington, D. C., and the state of Maryland outside Baltimore City.

It will be noted also that the percentage distribution of physicians in terms of weekly patient load is almost identical in Baltimore and Washington, the distribution in both instances being skewed in favor of the higher patient loads. The average weekly patient load carried by the physicians is almost the same in the two cities: 119 for Baltimore and 115 for Washington. For the Maryland counties the more rural areas of the state, the mean patient load is 132, higher than for either of the two cities.

Among the four age groups into which the general practitioners are classified there exist differences which are especially striking because they are found in each of the three populations examined. The highest average patient load is carried by the physicians between 35 and 44 years of age. The physicians under 35 demonstrate a slightly lower average but nevertheless higher than that for the ages 45 years and above. The men 65 years and above possess the lowest patient load, less than one half of that of the men between 35 and 44 years.

The differences in the patient load carried by the four age groups of physicians are best evident for the number of patients seen in the office but are also apparent for the patients seen at the hospital and at the patient's home. With reference to these observations it is of interest to point out that there is a positive and substantial correlation between the number of patients seen in the office and the number seen at hospitals and the homes of the patients. The coefficient of correlation of the two variables ranges from +0.41 to +0.66 for the four age groups of physicians in Washington, D. C., Baltimore City, and the Maryland counties. The correlation would indicate that the general practitioners who have a larger office practice also have more home and hospital visits to make.

Among the Washington, D. C., general practitioners, 75 per cent of the total average weekly patient load consists of office patients. The percentage is 69 for the Baltimore City general practitioners and 73 for the general practitioners of Maryland outside of Baltimore. Thus the Baltimore City practitioners

Chart 2—Average number of patients seen in one week by white male general practitioners by different age groups

make proportionately more home and hospital calls than do the physicians of the other two areas. The ratio of home to office calls can be used to express the same relationship. Among Baltimore City general practitioners the ratio equals 38 per cent while among the general practitioners of Washington, D. C. and

2 For the District of Columbia sample the records of the medical society were utilized for this information. For the Maryland sample the information reported in the 1942 Directory of the American Medical Association was used.

3 It is necessary to point out that Baltimore City is an independent political subdivision of Maryland and is not contained in any of the twenty-three counties of the state.

of the Maryland counties it equals 24 and 30 per cent respectively. There is a tendency for this ratio to increase with age that is the older general practitioners make relatively more home calls than do the younger ones. In the Washington, D. C. sample, the ratio is 24 per cent for the men under 35 years of age and 38 per cent for the men 65 years and older. In the Baltimore City sample, the ratio is 26 per cent for the former and 64 per cent for the latter age group, and among the practitioners of the Maryland counties, the ratios are 27 and 33 per cent for the two age groups in the order named.

The small number of Negro male and of female physicians both Negro and white does not permit adequate comparison with respect to age and specialty. The great majority of Negro physicians are general practitioners, but the female physicians are mixed specialists and general practitioners. The pertinent data for Washington, D. C., and Baltimore are presented in table 5. From the table it is seen that Baltimore Negro physicians carry a heavier patient load than the Washington ones, and the age effect already mentioned is rather pronounced in both groups. Among the female physicians it is found that the younger practitioners have a greater patient load than the older

TABLE 5—Average Weekly Patient Load of Negro Male and of Female Physicians

Age Group	Number of Physicians Giving Infor mation	Weekly Patient Load					
		Averages				Standard Deviations

All age	16	43	15	6	64	60	68

physicians. It is also observed that the Washington female physicians have a larger number of patients than the Baltimore ones, and both apparently carry a much lower patient load than the males.

PATIENT LOAD AND TYPE OF PRACTICE

In terms of the number of physicians involved, the major types of specialty represented by the practitioners include internal medicine, surgery, obstetrics and gynecology, pediatrics, ophthalmology and otorhinolaryngology⁴ and neurology and psychiatry. The other specialists are represented by so few physicians that their average patient loads are not discussed.

The data of table 6 reveal that all six stated groups of specialists practicing in Washington, D. C., have a slightly lower average patient load than the general practitioners. In Baltimore City instead it is found that the general practitioners carry a lower patient load on the average than do the pediatricians and the ophthalmologists and otorhinolaryngologists.

The differences between specialists and general practitioners relative to patient load is striking in the case of neurologists and psychiatrists, whose patient load is about one fourth that of the general practitioners. For both the Washington and the Baltimore neurologists and psychiatrists the men above 45 have a larger patient load than the men below that age. But for the remaining specialties, in general, the younger men have the greater patient load.

Other differences between specialists and general practitioners are observed with regard to the relation-ship of office calls to total calls. In particular, the ophthalmologists and otorhinolaryngologists in both cities studied see a very high proportion of their patients in the office. On the other hand the proportion of patients seen at home by pediatricians is above the average of that of the general practitioners.

* Less than 0.5

The standard deviation of the patient load of specialists is, with the exception of the surgeons of both cities and of the ophthalmologists and otorhinolaryngologists in Baltimore much smaller than that found in the case of general practitioners. This may well be due in part to the greater homogeneity of the activities of specialists in comparison with general practitioners.

4 These two specialties have been combined because of the large number of eye, ear, nose and throat specialists included in these samples.

PATIENT LOAD AND OFFICE WORKING TIME

Usable data on time spent in the office are available only for the Maryland physicians. The average time routinely spent in the office seeing patients each day is 52 hours for Baltimore general practitioners and 59 hours for the general practitioners of the Maryland counties (table 9). The average time differs somewhat for the several age groups, and the variation between age groups for hours in the office follows the same pattern as the variation relative to patient load (table 4). The practitioners 35-44 years old spend the highest average number of hours in the office seeing patients, the men 65 years and over spend the lowest. The men under 35 are second so far as concerns number of office working hours. Although the differences are not large, some significance can be attached to the fact that they are similar in the two samples.

The differences between the age groups not only reveal that the younger physicians have a higher patient load and spend

discussed. Only the ophthalmologists and otorhinolaryngologists, whose average daily office working time is 56 hours, spend more time in the office seeing patients than do general practitioners. The average daily office working time of the other groups is as follows: internal medicine 44 hours, surgery 44 hours, obstetrics and gynecology 37 hours, pediatrics 33 hours.

ESTIMATE OF PRESENT VOLUME OF MEDICAL CARE

The data on the patient load of physicians offer the possibility of arriving at a measure of the amount of medical services given by the physicians of a community to private patients. The product of the average weekly patient load by the total number of physicians of the community will give the number of persons who visited the physician or were visited by him during the week. If it is assumed that the physician's year is composed of fifty weeks, then the number of persons seen in one week multiplied by 50 will yield an estimate of the

more time in the office but also reveal that per unit of time spent in the office the younger physicians see more patients than the older. Thus, from table 9 it is seen that the younger physicians those below 45 years of age see in their offices about 20 patients a week for every hour daily spent in the office. This relative office patient load falls to about 9 patients weekly for every hour spent daily in the office by the men 65 years of age and over.

The relationship between the average number of patients seen in the office and the number of hours the practitioners spend in their offices is illustrated in chart 3, which deals only with the men under 65 years of age. The average number of weekly patients increases at an almost constant rate for each additional hour spent in the office. From 30 weekly office patients for the practitioners who spend two hours daily in the office the office patient load increases to an average of 140 patients for the men who spend eight hours in the office. Each additional hour means an average increment of 18 patients weekly, or, assuming a five day week, 3.6 patients daily. From the results it can be estimated that on the average the office visit lasts seventeen minutes per individual.

In Baltimore, the general practitioners spend more time in the office than do the majority of the groups of specialists

total number of calls or services rendered by the private practitioners in a year. The results of these computations for Baltimore City, the whole state of Maryland and Washington, D. C., are shown in table 7. An estimated total of 5,518,700 calls are made annually by the private practitioners of Baltimore and 4,864,450 by the practitioners of Washington, D. C. Thus an average of 62 services per person are furnished in Baltimore and 59 in Washington, D. C. The services given in Maryland outside of Baltimore City, amount to only 3.4 per person and Maryland as a whole thus receives 47 physicians' services per person annually. For the two large urban centers the average number of calls per person is nearly identical but much higher than that for the more rural areas of Maryland. The increase of medical services in relation to greater urbanism was observed by Collins⁵ in the material collected by the Committee on Costs of Medical Care. Collins' averages were lower than those obtained in the present sample, and the discrepancy may be due to several factors, among which are the facts that the survey by the Committee

5 Collins, S. D. Frequency and Volume of Doctors' Calls Among Males and Females in 9,000 Families Based on Nationwide Periodic Surveys, 1928-31. Pub. Health Rep. 55: 1977-2020 (Nov. 1) 1940. Reprint 2205.

on Costs of Medical Care was made over a decade ago, followed a completely different procedure and involved a different kind of population

The difference between urban and rural areas relative to the amount of medical care furnished not only may reflect differences in morbidity or in the mores with reference to demand for medical care, but also may be caused by the flow of patients from rural to urban areas. Therefore the differences observed in table 7 do not necessarily mean only that Washington and Baltimore residents receive more medical care than do the residents of the counties of Maryland but they also may mean that the physicians of the two cities furnish service to a substantial number of persons not resident there. For example, in the survey from which the Washington, D. C., data were acquired⁶ it was found that 15 per cent of the patients of the physicians who replied to the questionnaire were nonresidents of the District of Columbia. Correcting for this flow of patients would reduce the annual number of calls per person among Washington D. C. residents to 5. This average is not much larger than that computed for the state of Maryland.

Comparing Washington and Baltimore, one finds differences in the distribution of physicians according to type of practice and according to color and to sex. These differences are demonstrated in the total annual number of services given. Thus, although the populations of the two cities are almost of the same size, it is estimated that the general practitioners of Baltimore annually make 3,022,600 calls to private patients as compared with 1,771,000 made by the Washington general practitioners. On the other hand, a greater number of services are given by the Negro and female physicians and the internists

In the first place there are apparently age differences with regard to patient load and to office working time of physicians. Hence, the withdrawal of men below 45 years of age from a population has not the same effect as that of withdrawing men above that age. Not only do the younger men see a greater number of patients and spend more time in the office seeing

Chart 3—Average number of office patients seen in one week by Maryland general practitioners (white males under 65) according to daily number of office hours. The Maryland curve includes figures for Baltimore City.

TABLE 9—Average Number of Hours Spent in Office Seeing Patients (White Male General Practitioners)

of Washington than by the corresponding groups of physicians in Baltimore.

It has already been seen that the majority of the groups of specialists have a smaller patient load and shorter office working hours than do the general practitioners. However, a comparison between the percentage of estimated annual services given by the several types of practitioners and the percentage of each type of practitioner reveals a close parallelism. This is shown in table 8. Except for the neurologists and psychiatrists, who constitute 3 per cent of the private practitioners but give less than 1 per cent of the total physicians' services, there is on the whole little difference between the relative frequency of the specific types of practitioners and the proportional amount of medical services given by each type.

COMMENT

The data presented here concern the activities of physicians as they are manifest at present in the areas surveyed. Obviously, the situation described cannot be equal to prewar conditions. With the withdrawal of some 25 to 30 per cent of the physicians from these areas the average patient load per remaining physician has certainly increased, and it is probable that the increase may have affected the younger age groups more than the older. The data presented should be carefully evaluated in relation to the peculiarities of the times, but there is no doubt that the results of the analysis bring out certain important features pertinent to the solution of the problem of measuring civilian demands for medical care and of estimating numerical criteria for the selection of physicians from the population.

patients but they also see more patients in a given unit of time than do the older men. The general practitioners under 45 years of age have a patient load 25 to 50 per cent greater than that of other men between 45 and 64 years of age and more than twice as large as that of general practitioners 65 years and older. In Washington D. C. among the white male general practitioners, for example, although the men under 45 years constitute less than 50 per cent of the physicians, they see almost 60 per cent of the patients. These findings serve to emphasize the need for careful consideration of the

Chart 4—Estimated change in average patient load of remaining physicians as ratio of physicians to the population decreases. The Maryland curve includes figures for Baltimore City.

age distribution of the physicians of a community when preparing to establish the number that can be released for military service. For example, in a community containing two physicians one 35 and the other 65 years of age one could maintain that the removal of the younger man will mean the loss of not one half but of two thirds of the physicians.

⁶ Ciocco Antonio, Pond M. A. and Altman Isidore. A Survey of Practicing Physicians in Washington. M. Ann. District of Columbia 11: 454-457 (Nov.) 1942.

With reference to the specific problem of arriving at a measure of the civilian demand⁷ for medical services, data on the patient load of physicians offer a simple and direct approach if it is assumed that at present the demand does not exceed the capacity to meet it. The information on the patient load permits the calculation of the total medical services furnished to a popula-

the primary and most important problem of estimating how many physicians it is possible to withdraw from a population and still satisfy the present demand for physicians' services.

An adequate solution requires, in addition, a precise evaluation of the maximum patient load that physicians can be expected to carry. Once that maximum is known, then the number of physicians needed to satisfy the present civilian demand for medical care can be easily determined from data of the kind presented in table 10 and chart 4. The information collected in the present survey does not furnish a conclusive and definitive measure of the maximum patient load, but, mainly for the sake of illustrating the method to be employed, some tentative values can be derived from the results of the analysis.

For example, it could be assumed that private practitioners can be expected to work at most between 2,000 and 2,500 net hours annually. In a five day week and a fifty week year this would mean a working day of between eight and ten hours. It will be recalled that the general practitioners who spend eight hours in their office see on the average 140 patients weekly, and it can be calculated that those who spend nine hours in the office see an average of 158 patients weekly. Seeing patients in the office facilitates speed and economy of action, hence it can be reasoned that these values represent approximations of the average maximum patient load of private general practitioners.

According to the foregoing premises, the maximum number of patients that can be seen by a general practitioner would vary between 140 and 160 weekly, on the average. Let us return to chart 4 and table 10 to appreciate the significance of these maxima in terms of the ratio of physicians to the population and of the present patient load. A weekly average patient load of 140 would require a ratio of one physician to 960 persons in Washington, D. C., one to 970 in Baltimore and one to 1,315 in Maryland. A weekly average patient load of 160 requires instead a ratio of one physician to 1,060 persons in Washington, D. C., one to 1,085 in Baltimore and one to 1,475 in Maryland. From table 10 it will be seen that a weekly average patient load of 140 for Washington, D. C., represents an increase of approximately 22 per cent over the present patient load or, when the ages of the remaining general practitioners are considered of approximately 26 per cent. If instead 160 patients weekly are considered the maximum average patient load, then the increments over the present patient load become approximately 39 and 48 per cent, respectively. Similar results are obtained for Baltimore City and the state of Maryland.

To evaluate correctly these resulting increments, it should not be forgotten that already the present average patient load per physician represents an increase of perhaps 25 per cent over that of 1940. Thus, if the patient load of a group of physicians is

TABLE 11—Estimated Number of Specialists per Hundred Thousand Population for Specified Ratios of Physicians to Population

increased by 40 per cent for example, over that of the present it is actually increased by about 75 per cent over that existing in 1940. Therefore the pertinent question to be asked, before accepting any proposed value of the maximum patient load, is whether or not the remaining physicians are able to sustain the added burden.

When the upper limit of the ratio of all physicians to population is established in the manner indicated, an attempt can also be made to arrive at the ratio of the several types of practitioners needed for a population. Since the proportion of services

‡ Assuming that all withdrawals are below 45 years of age.

tion, as has already been shown and in addition offers a measure of the effects of the withdrawal of physicians in terms of the amount of work that will have to be assumed by the remaining physicians in order to provide the amount of services furnished at present.

Table 10 and chart 4 illustrate for Washington, D. C., Baltimore and the state of Maryland the relationship of the reduction in the ratio of physicians to population to the patient load of the remaining white male general practitioners. The effects of the reduction of physicians on the average patient load are almost the same in Baltimore and in Washington. For example, by reducing the ratio of physicians to population to 1:1,000, the average weekly patient load of the remaining general practitioners would be increased to 145 in Baltimore and 147 in Washington. For Maryland the relationship is established at a different level of ratio of physicians to the population since we are dealing with a combined rural and urban population.

In the last column of table 10 an attempt is made to measure the effects of the age differences in patient load in relation to the age selection of the physicians withdrawn from the population. Assuming that all the physicians withdrawn from civilian practice are below 45 years of age, the increase in the patient load due to the reduction of physicians has been computed on the basis of the patient load now carried by the men who remain. Thus an increase in the patient load of the general practitioners of Baltimore City to 180 patients per week means an increment of 51 per cent if the increase is calculated from the all age average of 119, and of 75 per cent when the present patient load of the remaining practitioners is taken into account.

Since the data of table 7 and chart 4 furnish a measure of the amount of work that would have to be assumed by the practitioners remaining in a population after the withdrawal of a stated number, a first step is available toward the solution of

7 The demand for medical services is not to be confused with the need for such services. Obviously the number of patients actually seen by physicians will not exceed under ideal conditions equal the number of persons needing medical care.

rendered by each of the several types of practitioners is essentially equal to the proportion of each type of practitioner, it can be inferred that any decrease in the total number of physicians will affect equally the general practitioners and each of the groups of specialists. Thus, by maintaining constant the relative number of each kind of specialists, the decrease in absolute number can be estimated in relation to the decreases in total number of physicians. Table 11 presents the results of estimating the number of specialists per hundred thousand population when the ratio of physicians to population is reduced to specified limits. If it is accepted that the ratio of physicians to population can be reduced to 1,000 in urban centers such as Baltimore and Washington, according to the calculations presented in table 11 it will be necessary to retain for each 100,000 persons, eight to nine internists, seven to eight surgeons, six to seven obstetricians and gynecologists and so on. In a state which contains both urban and rural elements, a relatively smaller number will be required to furnish the same amount of services as that currently provided.

It is important to realize that these results are based in part on certain assumptions that have not been fully proved and are presented here mainly to illustrate the method of approach. However, it seems clear that the results of the study warrant the conclusion that data on the patient load of physicians offer a simple and direct approach to a solution of one aspect of the problems arising from the withdrawal of physicians for the armed services. When all is considered, the amount of medical care that the population can receive depends not only on the number but also on the working capacity of the physicians practicing in the population.

SUMMARY

Data on the number of patients seen in one week by physicians in private practice were obtained in a survey conducted in the District of Columbia and in the state of Maryland by mailed questionnaire. In Maryland, data were also secured on the number of hours a day routinely spent in the office seeing patients.

Replies were received from 60 and 66 per cent of the physicians in the District of Columbia and Maryland respectively. The distribution of replies by type of practice and age, sex and color of the practitioners supports the belief that on the whole a representative sample was obtained of the physician population questioned.

The average weekly patient load among general practitioners is 115 patients in Washington, 119 in Baltimore and 132 in Maryland outside of Baltimore. Differences by age in these areas are striking. Physicians 65 years and older have an average patient load of less than half the average for men between 35 and 44, the latter being the group with the highest number of patients. Physicians under 35 had a higher average patient load than the group 45 to 64 years old.

Approximately 70 to 75 per cent of the patients attended by general practitioners are seen in the office. There is a strong tendency for the older men to make relatively more home calls than the younger men.

On the whole, specialists carry a somewhat smaller patient load than do general practitioners. For psychiatrists and neurologists the patient load is very low, since by the nature of their work the number of patients they can see in one week is necessarily small. The younger specialists apparently see the greater number of patients.

General practitioners of Maryland spend five to six hours daily on the average in routine office practice. Specialists spend about four. It is found that the more time spent in the office the more patients are seen, with the number of patients increasing at an almost constant rate for each additional hour.

From the data collected estimates can be made of the total amount of medical services given by the physicians of the communities involved and thus a measure obtained of the effect of withdrawing physicians for the armed forces. The data permit also an estimate of the maximum volume of services that a physician can be expected to furnish. Such information should prove valuable in establishing quantitative criteria to determine the essentiality or availability of physicians in relation to the needs of the community.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE
HOWARD A. CARTER, Secretary

THE THERAPEUTIC VALUE OF ULTRAVIOLET RADIATION

(Continued from page 179)

UNDESIRABLE RESULTS IN DERMATOLOGY

Many of the inflammations, especially when acute or subacute (eczema, psoriasis and the like), may be made more acute or to spread or change character by too vigorous treatment with ultraviolet radiation. For instance, a patch of subacute eczema of any type may change to exudative eczema and may then become more or less generalized (infectious eczematoid dermatitis). Although a patch of chronic psoriasis will usually tolerate and may even be benefited by an erythema dose on the other hand the patch may spread over the area of erythema if the normal skin is not protected. When treating individual lesions of any dermatosis it is advisable to protect the surrounding normal skin. Generalized psoriasis, especially if it is of the more acute or inflammatory type, if treated too vigorously, may change to universal psoriasis or dermatitis exfoliativa. The same phenomenon is observed at times in cases of eczema. It is admitted that vigorous treatment may at times make large patches of psoriasis and eczema disappear but such treatment is risky.

Large doses of solar radiation and of artificially produced ultraviolet radiation may precipitate attacks of herpes simplex and lupus erythematosus. Erythema and even suberythema doses of ultraviolet radiation applied to the normal skin of patients suffering from lupus erythematosus may cause the development of the disseminated type of the disease. In certain individuals infra-red rays or any form of heat applied for a considerable period will provoke a mottled erythema and pigmentation known as erythema ab igne.

The so-called sailors' skin or farmers' skin is a pre-eruptive condition of the skin of the exposed parts occurring in persons who are exposed to solar radiation more or less constantly for many years. The skin is wrinkled and dry and keratotic of the senile type are likely to develop. These in turn may frequently change to cancer. Farmers' skin may consist only of permanent freckles most commonly seen on the shoulders, the upper part of the back, the chest and the backs of the hands. These freckles are not especially dangerous but occasionally one may change to a keratosis and later to cancer. Farmers' skin in many ways resembles the so-called x-ray or radium skin (x-ray or radium sequelae). It also resembles xeroderma pigmentosum a condition due to exceedingly low cutaneous tolerance to light.

It becomes manifest on the exposed parts of such patients early in life being most pronounced on the face. The eyes are congested the skin is dry and atrophic ectropion develops and there are innumerable freckles of the permanent type and keratoses of the senile type. Curiously, many of the keratoses change to basal cell epitheliomas rather than to epitheliomas of the prickle cell variety. Patients who have a low cutaneous tolerance to light not only should avoid direct sunlight and artificially produced ultraviolet radiation but should avoid strong daylight because diffused sunlight and reflected light from snow, water and sand contain large amounts of ultraviolet radiation. If such patients find it necessary at times to be exposed to strong solar light, the face and hands should be protected with veils, walnut stain, an alcoholic solution of glycerite of tannin or cream containing dark substances, such as burnt sugar or ichthammol. A preparation which has been found effective to protect the skin against the effects of ultraviolet radiation is the following:

R	Phenyl salicylate	1 Gm	gr 5
	Tannic acid	5 Gm	5
	Wool fat		
	Petrolatum flavum	aa q s ad 100 Gm	3 i

For very mild cases, a coating of yellow petrolatum followed perhaps by a dark colored powder may provide sufficient protection. The fad of exposing bodies of children to solar radiation and artificially produced ultraviolet radiation daily and indefinitely without medical supervision may eventually give rise to farmers' skin in a small percentage of children who happen to be idiosyncratic.

Hydroa vacciniforme is a rare bullous disease, mostly of children, limited to the exposed parts and occurring during the spring, summer and fall. The etiology is supposed to be associated with the effect of light on the skin of a susceptible person. Hematoporphyrin has been found in the urine of these patients and it is thought that this and other substances may have something to do with sensitization to light. In the same category may be placed pellagra and summer prurigo melanosis, simulating chloasma and argyria, has been reported following sunburn.

Certain substances when injected into the body or painted on the skin appear to cause sensitization to light. There is one instance in the literature (Meyer-Betz) in which hematoporphyrin was injected. Exposure to the light caused edema of the hands and face. Eosin when painted on the skin combined with exposure to light may result in severe dermatitis. Oil of bergamot and perfumes on the skin may be followed by dermatitis and pigmentation on even mild exposure to sunlight or ultraviolet radiation (Berlock dermatitis). Attempts in this way have been made to modify or cure leukoderma with occasional success.

Skin affected with certain diseases especially with the desquamating fungous diseases such as chromophytosis when subjected to radiation that causes tanning may assume a peculiar appearance, so much so as to interfere with diagnosis. Chromophytosis is a good example. The patches of eruption are of a yellowish brown and the surrounding normal skin tans so that its color matches fairly well that of the affected areas. The patches of disease do not tan because the slightly thickened horny layer absorbs the radiation. Exfoliation of this horny layer leaves white patches which are in sharp contrast to the surrounding tanned skin. Urticaria and certain forms of recurrent acute dermatitis of the face, neck, forearms and hands are at times thought to be due to sensitization to light.

Conjunctivitis and other eye troubles may be caused by excessive exposure to direct sunlight, reflected sunlight and radiation from ultraviolet generators. Ultraviolet rays from the so called cold quartz lamp are particularly prone to produce conjunctivitis. Depending on the exposure and the susceptibility, the inflammation may be slight or severe, transient or persistent. Arctic explorers and mountaineers occasionally have snow blindness. In the industrial field, acetylene and arc welders have trouble with their eyes unless they wear goggles.

Ordinary glass will protect the eyes from ultraviolet rays, but, for protection from all ultraviolet wavelengths and visible light, it is preferable to use glass of a dark color—amber, green or black. It is important that the goggles be edged with soft opaque material that will obstruct the passage of light between the goggles and the skin.

SUNBURN

Ordinary sunburn is known as erythema solare and dermatitis actinica. In this category may of course, be placed burns caused by ultraviolet radiation from any source. The reaction may consist of no more than a slight erythema—a flush—or definite erythema accompanied by a sensation of heat followed in a few days or a week by itching and exfoliation. If the reaction is more severe there is edema, vesiculation, erosion and perhaps exudation. The subjective symptoms are burning and itching. Depending on the degree of reaction, spontaneous recovery occurs, as a rule in from a few days to a few weeks. Occasionally recovery is delayed. Erythema and edema have been known to endure for months. Regardless of severity, in the absence of complications sunburn does not produce a scar. When the area burned is extensive, there may be constitutional symptoms consisting of malaise, headache, fever and vomiting. In fact, a more or less severe constitutional reaction may occur

in the absence of a burn when radiation is applied to the entire body. Such a reaction indicates that the dose is too high for the individual.

Mild and moderate local sunburn requires little if any treatment. Ointment of rose water or almond emulsion may allay the sensations of burning and dryness. When such a burn is extensive and especially when accompanied by constitutional symptoms, the patient may have to spend a few days in bed. Whether the burn is local or more or less generalized, the type of topical treatment indicated depends on the cutaneous objective and subjective symptoms. Constant wet dressings of boric acid, sodium bicarbonate, watery extract of witch hazel or diluted solution of aluminum acetate are indicated when there is vesiculation, erosion and exudation or when the burning sensation is distressing. When the skin is inflamed and dry, applications of the following lotion may be prescribed:

1. Zinc oxide			
Magnesium carbonate	77	80 Gm	3 ii
Alcohol		150 cc	i s
Menthol		0.3 Gm	gr. iv
Phenol		20 cc	i s s
Distilled water q. s.	120	120 cc	i s

Uncented cold cream containing 1 gram (0.06 Gm) of menthol and 1 drachm (4 Gm) of petrolatum or hydrous wool fat to the ounce (30 Gm) may be used for the same purpose.

Tan and ordinary freckles disappear completely in time, provided light is avoided. Their disappearance can be hastened by the application of lotions and creams that encourage desquamation. Formulas for such remedies are in all textbooks on dermatology.

METABOLISM

The blood sugar of normal men is not influenced to any extent by ultraviolet irradiation. In some persons with diabetes the blood sugar may be temporarily diminished. The decrease is probably due to increased excretion of insulin and may be accompanied by increased storage of glycogen in the heart, liver and muscle.

It is the opinion of most authorities that irradiation of lactating women increases to some extent the quantity and antirachitic potency of the milk.

Irradiation of moderate intensity increases endogenous nitrogen metabolism. Residual nitrogen is usually diminished. The excretion of uric acid is said to increase giving support to the use of ultraviolet in the treatment of gout. Ultraviolet irradiation may double the fat content of the blood, cholesterol increases by 30 per cent.

The effect of ultraviolet irradiation on respiration is to make it easier, deeper and less frequent although total ventilation per minute remains constant. It is generally accepted that basal metabolism is not influenced by ultraviolet irradiation. When an increase in metabolic rate is observed on isolating the nude body it is due predominantly to the cooling effect of the moving air. If the air temperature is high with little or no air movement the chemical heat regulating mechanism is brought into action and the metabolic rate diminishes.

Ultraviolet irradiation exerts a glycogen storing effect, preventing the lowering of the respiratory quotient after muscular exercise which lowering is due to glycogen impoverishment.

Practically all attempts to show effects of light on normal growth processes of man and animals have been negative. Animals will grow as well in darkness as in light if the diet is complete.

Ultraviolet has no influence on the activity of the thyroid. The goiter producing power of cabbage is reported to be increased by ultraviolet irradiation.

The antirachitic effect of ultraviolet occurs in the lowermost cells of the horny layer and in the prickly cells of the malpighian layer while the production of erythema takes place in the basal cells (germinativum) of the malpighian layer and in the corium. The horny, clear and granular layers act as filters. Ergosterol and cholesterol can be activated by ultraviolet rays which pass

through the epidermal layer of the skin. Blood in the superficial capillaries absorbs only a small percentage of energy incident on the skin.

The "burn" produced by ultraviolet takes a few hours to appear and the longest wavelength that can produce it is about 3,150 angstroms. The curve representing relative effectiveness of different wavelengths rises to a maximum at 2,967 angstroms, descends to a minimum at 2,800 angstroms, then rises again to a small maximum near 2,500 to 2,450 angstroms and extends to an undetermined shorter wavelength. Blondes are from 40 to 170 per cent more sensitive than brunets, men 20 per cent more sensitive than women. Persons between 20 and 50 are more sensitive than those younger or older. There is an average maximum sensitivity in March-April and in October-November. A person with an unstable nervous system, an overactive thyroid gland, elevated blood pressure or active tuberculosis shows increased sensitivity. The sensitivity increases at the menses—a maximum being reached on the first day of the cycle—and then declines to normal. After the second month of pregnancy the sensitivity definitely increases until the seventh after which it diminishes somewhat, being still high at term. Increased sensitivity is correlated with thyroid hyperactivity and with an increased number of open capillaries in the skin. An acid diet increases sensitivity. Salts exert a protective action, an acid saline less than an alkaline.

Erythema shows the reactions of the 'triple response' and depends on the setting free of H substance. The acidity of the gastric juice increases simultaneously with its beginning.

Pigment formation and therapeutic benefit are independent, coordinate phenomena proceeding simultaneously in the same direction. Pigment formation is dependent on individual factors: race, coloring, constitution and body function. It can be used as an index in treatment. It is also a measure of adaptation, since pigment formation, horny layer thickening and chemical alterations of the skin cell proteins run parallel.

THE EYE

The cornea begins to absorb at 3,600 angstroms and transmits to between 2,950 and 3,000 angstroms, and the crystalline lens transmits to 3,060-4,190 angstroms, according to age. The vitreous transmits wavelengths as short as 2,300 angstroms, with a broad absorption band from 2,500 to 2,800 angstroms. The lens absorbs wavelengths as short as 2,950 angstroms with no ill effects, but shorter wavelengths produce a severe ophthalmia. Sunlight is ordinarily harmless, but when the ultraviolet component is increased by reflection, as from sand, water, ice or snow, it produces "snow blindness." Glowing arcs and metals which emit energy shorter than 2,950 angstroms are injurious and special ultraviolet absorbing glasses should be worn. The damage is usually limited to conjunctivitis and blepharitis with pricking pain and uncomfortable foreign body sensation. Edema and contraction of the lids and corneal erosion may occur. Long continued exposure to intense ultraviolet may produce functional disturbances, such as color scotomas and constriction of the peripheral field. Amblyopia and central scotoma have been noted in "snow blindness." Eclipse blindness is due to intense local action of infra red rays.

It is still a question as to whether intense ultraviolet produces lenticular cataract. Many incline to the view that glass workers' cataract is due to the intense infra-red rays which interfere with the nutritional functions of the ciliary body. It is probable that the higher incidence of cataracts in workers exposed to molten glass and metals is due to increased rate of precipitation of light denatured protein when the lens is heated above body temperature by exposure to large sources of radiant heat and when low concentrations of calcium, or other substances producing a similar effect, are present.

Claims have been made that some persons can see wavelengths as short as 3,130 angstroms. This is due to excitation of the retina by fluorescent (longer) wavelengths. The aphakic eye sees shorter wavelengths than the normal eye.

PHOTODYNAMIC OR OPTICAL SENSITIZATION PATHOLOGY

It is possible to sensitize living cells, like photographic plates, and thus produce abnormal conditions in which light or luminous rays and longer ultraviolet rays are as active as the shorter

ultraviolet. The effective wavelengths are those absorbed by the sensitizer. Sensitization occurs at 4,000-5,800, 3,650-3,150 and 2,500 angstroms. The sensitizers are exogenous taken in with the food and endogenous arising within the organism. Most sensitizing substances are fluorescent but fluorescence is not the cause. Ultraviolet effects can occur either in the presence or in the absence of oxygen, but the photodynamic effects occur only in its presence. Among photodynamic sensitizers are erythrosin, rose bengal, rhodamin, anthracene derivatives, acridine dyes, methylene blue, quinone, chlorophyll, hypericin and the porphyrins. Gold salts and chemicals of the sulfonamide group are also sensitizers.

Continued and prolonged exposure to sunlight or to the energy of artificial sources containing much ultraviolet may cause systemic disturbances as well as inflammatory and degenerative changes in the skin. The systemic disturbances are not understood but deaths of infants following short exposure have been reported and severe reactions in adults.

Photodynamic 'triple response' produced by intradermally injecting rose bengal and hematoporphyrin is similar in appearance to urticaria solara and is produced by the wavelengths absorbed by the particular sensitizer. The response is immediate. It is followed by pigmentation and does not occur in the absence of oxygen. The mechanism of the urticarial response includes a photochemical reaction not definitely affected by temperature and a thermal reaction greatly modified by changes in temperature. The latter is probably due to the action of the H-like substance on the small vessels of the skin. The photosensitizer is a carotenoid pigment.

The relation of ultraviolet to pellagra is difficult to evaluate. The clinical impression that sunlight is harmful to the pellagrins has been confirmed again by Smith and Ruskin according to whom the seasonal incidence of pellagra is conditioned by the degree of dietary deficiency and the intensity of the solar radiation. Exposure of a susceptible subject, who has been subsisting on a deficient diet, to the sun's rays precipitates the acute manifestations of pellagra. Pellagrous lesions however occur in the absence of sunlight and they may heal in the presence of exposure to direct sunlight or to ultraviolet radiation. Spies suggests that pellagra is a systemic condition which in itself is the real cause of pellagrous dermatitis and not exposure to the rays of the sun. Under conditions sunlight may act as an irritant and precipitate cutaneous lesions. But any kind of irritant may predispose an area to localization of the dermatitis, the absence of which however indicates little as to the cure of the disease. Porphyrinuria in pellagra has been described.

Repeated irritation by ultraviolet rays can cause chronic lesions, which may be precancerous such as keratosis senilis and xeroderma pigmentosum. It is an open question as to whether xeroderma pigmentosum and skin cancer are really associated with photodynamic action. Roffo believes that in the carcinogenic production of skin cancer by ultraviolet the photodynamic action of cholesterol plays the most important part. The photoactivity is due to the emanation of hydrogen peroxide or similar products. Korbler does not believe that the frequency of skin cancer is due solely to exposure to strong sunlight, although it may result in sensitization due to local increase in porphyrin.

The action of radiation is paradoxical in this regard. If the cells of the basal layer of the skin receive an excessive quantity of radiant energy the two protective processes of cornification and pigmentation become abnormally great (hyperkeratosis and hyperpigmentation) and a third degenerative process starts. People lacking in pigment or much exposed to ultraviolet rays show the highest percentage of skin cancer. The developing neoplasm occurs in the place of greatest proliferation, beginning in a wartlike hyperkeratosis, a precancerous change. A cancer develops from a precancerous lesion not only as a result of a continuation of the initial insult but as a result of any continued trauma. Thus ultraviolet rays do not cause cancer in themselves. They produce characteristic cell changes leading to precancerous lesions in the skin. Any irritation, including continuously and excessively applied ultraviolet rays, can cause the precancerous change to become malignant.

TREATMENT OF CEREBROSPINAL FEVER

The current increase in the number of cases of meningococcal meningitis in various parts of the country, which was to be expected in view of the military and industrial mobilization has emphasized recent advances in the treatment of the disease. These improvements depend almost wholly on the use of the sulfonamide compounds. Until recently many clinicians experienced in this disease advised combined treatment with some form of antiserum and a sulfonamide compound at least for the more serious cases. However, the shift from intraspinal to intravenous serum therapy, advocated especially by Henrich and Hoyle had generally prevailed. Accumulation of data seems now to show that drug treatment alone will bring better results than combination with such an agent as foreign serum, which, even when given intravenously may initiate a considerable number of reactions.

In England, for example a statistically adequate number of patients treated with serum alone gave a fatality of 36.6 per cent as a whole. Of those under 1 year of age 67.2 per cent died of those from 1 to 4 years 38.6 per cent and of those from 5 to 14 years 22.7 per cent. With sulfonamide compounds plus serum, of those under 1 year 32.5 per cent died from 1 to 4 years 16.5 per cent from 5 to 14 years 8.4 per cent, from 15 to 24 years 4.3 per cent, from 24 to 44 years 14.1 per cent and 45 years and over 32.3 per cent, with a total fatality of 13.8 per cent. Treatment with sulfonamide compounds alone gave better rates in each age group: under 1 year 22.4 per cent, from 1 to 4 years 12.3 per cent from 5 to 14 years 5.5 per cent, from 15 to 24 years 2.5 per cent, from 25 to 44 years 6.6 per cent and 45 years and over 28.8 per cent, with a total fatality of 9.2 per cent. Aside from the rare and practically always fatal cases of Waterhouse-Friderichsen¹ syndrome with circulatory collapse, hem-

orrhage into the adrenals and hemorrhagic rash, the prompt diagnosis and early vigorous treatment, preferably with sulfadiazine, will save cases which had fatal prognosis with serum therapy, and in practically all cases recovery is much more prompt.

Other sulfonamide compounds may be used instead of sulfadiazine, including sulfathiazole, which was formerly held to be less effective because it was less uniformly excreted into the cerebrospinal fluid. Most important is the prompt securing of a high blood concentration of 15 mg per hundred cubic centimeters. Lumbar puncture is necessary practically only for initial diagnosis and an attempt should be made to find the organism by blood culture. The proper dosage of the sulfonamides is provided in detail in New and Nonofficial Remedies, 1942 pages 139 to 166.

INTELLECTUAL WORKERS AND PHYSICAL EXERCISE

Few studies have been made to determine the amount and nature of physical exertion which is optimal for those in sedentary occupations involving primarily concentrated and prolonged activities of the higher mental centers. Observation leads to the conclusion that most persons engaged in intellectual occupations take too little physical exercise for maximum health. Most medical students, for example, are inclined to indulge little or not at all in physical exercise. Those engaged in intellectual endeavors report that strenuous exertion (usually when they are not used to it) results in an appreciable decrease in ability to make constructive intellectual efforts during the immediately subsequent hours or even days. Although such observations cannot be used as scientific evidence the problem of balancing physical conditioning with maximum intellectual output is particularly pressing today when the curricula of schools devoted to advanced education are being modified to include conditioning for military service.

The armed forces plan to induct all physically fit boys 18 years of age or older. By methods of selection which have not yet been announced in detail a number of these young men will be selected to attend colleges and universities. While attending these institutions they will be expected to engage in strenuous and prolonged intellectual endeavors. During this period they are to be paid and housed by the armed service involved and will be just as much in the military service as those in camp or at the front. They will be required, no doubt to take certain physical hardening courses and sports, probably provided for specifically by the respective service involved.

Good physical condition is favorable rather than detrimental to intellectual work. Nevertheless the primary purpose of placing these soldiers in colleges and universities rather than at the battle fronts is to give them the intellectual training which they can receive

only from the former source. The physical "conditioning," therefore, is the secondary rather than the primary consideration. The intensity and amount of exercise for the soldier-student should be subordinated to the intellectual training. In determining the amount of exercise required of soldiers in colleges and universities, cognizance must be taken of individual variability and of the hours and nature of mental concentration required. The program of physical training of student-soldiers must be carefully controlled with a view to determining the best combination. If the physical training interferes with the maximum utilization of the educational facilities, the major purpose of the announced program will have been hindered.

AMERICAN SOCIETY FOR RESEARCH IN PSYCHOSOMATIC PROBLEMS

In recent years the development of medicine has revealed increasing interest in the patient as a whole. Whereas recent discoveries in pharmacology, biochemistry and endocrinology may be more spectacular, they are likely to make us overlook the steadily growing need of integrating all this specialized knowledge in the light of the functions and structure of the total organism. Logically psychiatry became the focus for crystallization of these unifying tendencies. Dr. William Allen White pointed out that psychiatry deals with the total reactions of the organism. In somatic medicine the patient's stomach, liver or blood vessels are the doctor's concern, in psychiatry the patient's actions are investigated. Psychosomatic medicine attempts to bring together these two points of view. In the psychosomatic approach the investigators seek to find the relationship between what the stomach is doing and what the patient as a whole is doing. How do the patient's emotions, his effort, hopes, discouragements and anxieties influence the different parts of his body? Psychosomatic medicine, however, is not a new specialty, the gradual penetration of the psychiatric point of view into general medical thought will cause the medical specialties to take the lead in exploring the psychologic component in disease.

The journal *Psychosomatic Medicine* says

Emphasis is put on the thesis that there is no logical distinction between mind and body; mental and physical. It is assumed that the complex neurophysiology of mood, instinct and intellect differs from other physiology in degree of complexity but not in quality. Hence again divisions of medical disciplines into physiology, neurology, internal medicine, psychiatry and psychology may be convenient for academic administration but biologically and philosophically these divisions have no validity. It takes for granted that psychic and somatic phenomena take place in the same biological system and are probably two aspects of the same process that psychological phenomena should be studied in their psychological causality with intrinsically psychological methods and physiological phenomena in their physical causality with the methods of physics and chemistry.

The psychomatic interest in medicine is not novel. Such ancient expressions as melancholia (*melas* black,

chole bile) reflect concepts concerning the relation of mental symptoms to bodily functions. New in the present psychosomatic movement is the integration of advanced methods of physiologic and clinical investigation with modern methods of dynamic psychology. The two avenues of research—the somatic and the psychologic—meet now on the level of present day knowledge.

Understanding of the patient's mental condition in the past was primarily a question of intuition, usually called the art of medicine or, in its more superficial form, 'bedside manner'. Psychosomatic research strives to transmute this art into a science, basing conclusions on well established principles affecting the relationship of emotions and bodily functions.

During the past ten years various research centers have focused their investigative work on the study of psychosomatic conditions.¹ The impetus of the war has greatly increased this interest. Probably few physicians realize how many such centers are now active in this field. Among the older medical projects have been those at Presbyterian Hospital in New York, the Institute for Psychoanalysis in Chicago and the Massachusetts General Hospital in Boston. Dr. Sigmund Weiss, before his untimely death, had planned a series of investigations. The studies already completed have concerned cardiovascular diseases, injury from accident, gastrointestinal disorders, diabetes mellitus, asthma and hay fever, as well as biologic processes. Correlation between emotional factors and the ovarian cycle has been a project of special note. Studies by psychologists and physiologists on animals, following the lead created by investigation of the conditioned reflex, have contributed much, for example the work of H. S. Laddell and his group at Cornell University and of W. Horsley Gantt and Curt P. Richter at Johns Hopkins University.

On Dec. 18, 1942, an inaugural meeting of the American Society for Research in Psychosomatic Problems was held in New York in conjunction with the annual meeting of the Association for Research in Nervous and Mental Diseases. This meeting was organized by the board of editors of *Psychosomatic Medicine*. An incentive for the foundation of this new society was the growing interest of the armed forces in the study and treatment of psychosomatic conditions. Disturbances such as air neurosis and the more acute forms of 'pilot's fatigue' are primarily of psychosomatic nature and constitute one of the major problems of aviation medicine. The American Society for Research in Psychosomatic Problems attempts to provide a platform for the exchange of ideas and experiences in this vital and rapidly expanding approach to medicine.

VITAMIN D AND DIHYDROTACHYSTEROL

Among the products derived from ergosterol on irradiation are two compounds with closely similar structure, calciferol and tachysterol. The former, known as vitamin D₂ in the European literature, is known here, when dissolved in oil, as viosterol. About twelve years ago the suggestion was made that the toxic effects of overdosage with irradiated ergosterol were due to something other than vitamin D: an active calcifying factor was discovered which would not cure rickets. This substance was identified as a dihydrotachysterol, a derivative of tachysterol. This substance, known also as A. T. 10, has the property of increasing the level of serum calcium and also of causing a definite urinary excretion of phosphorus, properties which suggested its use in human parathyroid tetany, with highly favorable results.¹

The early claims that dihydrotachysterol was ineffective in curing rickets were reinvestigated by Shohl and his co-workers² who concluded that it is effective in curing the low calcium type of experimental rickets, the high calcium type is not as susceptible to cure by dihydrotachysterol, though large doses show an effect. Nevertheless the Harvard investigators believe that dihydrotachysterol resembles vitamin D more than it does the hormone of parathyroid as regards the effects on serum calcium and phosphorus. The kind of experimental animal employed exerts a pronounced influence on the relative actions of dihydrotachysterol and vitamin D. Correll and Wise,³ who used chicks in their studies, observed that, when compared on the basis of rat units, dihydrotachysterol was somewhat more potent for chicks than is cod liver oil and much more potent than the vitamin D from irradiated ergosterol. The calcium-phosphorus metabolism of the chick is more responsive to dihydrotachysterol than to vitamin D from the usual sources.

A still further differentiation between dihydrotachysterol and vitamin D has been reported by the Harrisons.⁴ Through the experimental device of comparing creatinine clearance with phosphate clearance, the magnitude of reabsorption of phosphate in the renal tubules has been estimated. In normal animals this maximum rate under controlled conditions is increased by the administration of vitamin D thus serving to support the level of phosphate in the blood. After dihydrotachysterol is given, the maximum phosphate absorption rate remains unchanged. On the basis of these studies it is concluded that vitamin D is essential

for certain cellular functions in the body and cannot be replaced by dihydrotachysterol. Indeed, the point is made that the characteristic action of dihydrotachysterol depends on the presence of vitamin D.

Thus it has been possible, with further research, to indicate functional differences between these compounds, which grossly show considerable similarity. Furthermore, investigations of the comparative activity of the two substances, already of proved worth in therapeutics, have emphasized again the high specificity of biologic function conditioned by slight changes in the structure of chemical agents.

Current Comment

RESERVE PROTEIN IN THE LIVER

In his classic paper on glycogen in 1903 Pfluger¹ suggested that the liver might serve as a storehouse for protein as well as for carbohydrate. Experimental evidence has accumulated which indicates that the contention of Pfluger was correct. In 1906 Saitz² showed that the feeding of protein to fasted experimental animals resulted in an increase in liver protein which in a degree was comparable to the augmentation of liver glycogen that follows the administration of carbohydrate to fasted animals. In more modern work Addis and his co-workers³ have studied the protein content of the tissue of animals fed different amounts of protein daily for a number of days. As the amount of protein ingested by the animals was increased the proportion allocated to the liver, blood serum and kidney increased, while there was a slight fall in the proportion allotted to the carcass. The protein enrichment of the liver which follows the administration of high protein diets is associated not only with hyperplasia or hypertrophy but also with an increased content of protein per unit weight of tissue.⁴ Moreover, the relative loss of protein during abstention from food is greatest for the liver. During a seven day fast the livers of rats lose 40 per cent of their protein as compared to a loss of 20 per cent for the kidneys, 8 per cent for muscle, skin and skeleton and 0 per cent for the eyes, testicles and adrenals. Deposit protein in the liver is apparently not made of any particular protein fraction. The studies of Luck⁴ show that all the liver proteins, including albumin, euglobulin and pseudoglobulin, participate equally in the function of storage. It has been claimed, however, that storage protein can be differentiated microscopically from structural protein, the former having a droplet structure in the liver cells.⁵ The importance of the protein stores of the body is becoming increasingly appreciated. The reserve protein helps to

protect the liver against injury by toxic agents. Thus, twenty minutes of chloroform anesthesia are usually fatal to protein depleted dogs, while well fed animals tolerate one hour of anesthesia with little injury to the liver.⁷ The experimental hepatic cirrhosis which is produced in rats fed a low protein diet and given dilute alcohol to drink for a protracted period may be prevented if the amount of protein in the diet of the animals is increased.⁸ These examples are typical of a large number of comparable observations. Reserve stores of protein are important. The role played by the liver in this connection adds one more function to the long list of functions known to be performed by this organ. The observed relationship between an inadequate amount of dietary protein, the consequent low protein reserve and enhanced susceptibility to hepatic injury by a variety of toxic agents is noteworthy.

B VITAMINS IN CANCEROUS TISSUES

The occurrence of the vitamins of the vitamin B complex in all forms of living matter constitutes a strong presumptive evidence of their essential nature for the fundamental vital processes. It has been demonstrated that riboflavin plays a part in cellular oxidation. Warburg showed that the oxidation processes in cancerous tissues differed significantly from those in noncancerous tissues. Investigators at the University of Texas Biochemical Institute determined the distribution of the enzymes concerned with cellular oxidations in different types of cancer in an attempt to evaluate the significance of the results in terms of the transformation to the cancerous condition. Pollack and his associates¹ made riboflavin assays on a variety of human and animal tumors and on noncancerous tissues. Most of the cancers were found to contain about 2 to 3 micrograms of riboflavin per gram of moist tissue, the lowest value being 1.1 and the highest 7.4. The riboflavin content of cancers appears to be of about the same order of magnitude as those of brain, lung, spleen and muscle, and much below those of liver, heart and kidney. Noncancerous tissues require nicotinic acid for their essential functions, but little is known about the requirements of cancerous tissue. Taylor and his co-workers² found that in noncancerous tissue the nicotinic acid content amounted to 18 to 178 micrograms per gram of fresh tissue, while the range for the cancerous tissue was from 13 to 59 micrograms per gram, with most of the values between 18 and 29 micrograms per gram. They therefore conclude that the transformation to the cancerous state involves a decrease in nicotinic acid content. Whether this signifies low

utilization of this vitamin or low storage capacity and efficient utilization is not clear. The comparative constancy of the vitamin level in tumors may be an indication of the essential nature of the vitamin for cancer metabolism. Biotin has considerable interest as a possible essential catalyst for cancerous processes. Pollack and his co-workers³ found that the biotin content of cancerous tissue was never as high as that of kidney or liver and mostly was lower than that of heart. The biotin level of cancerous tissue appeared to be approximately of the same order as that of brain, lung, spleen and muscle. In the case of hepatoma induced by p-dimethylaminoazobenzene the cancer contained much less biotin than the control tissue. None of the cancers studied can therefore be classified as a biotin rich tissue. Cancers apparently neither particularly require nor are associated with a high biotin content. Investigations by Taylor and his co-workers⁴ into the role of pantothenic acid demonstrated that a large drop in vitamin content occurs in the transformation of rat liver to hepatoma by feeding p-dimethylaminoazobenzene. Almost all the human and rat cancers contained about the same amount of pantothenic acid as did noncancerous spleen, lung and skeletal muscle, which are decidedly poorer in this factor than liver, heart, kidney and brain. The results indicate that cancerous tissues probably do not have any greater need for pantothenic acid than do noncancerous tissues.

FLUCTUATIONS IN HYPERTENSION

Extreme fluctuations of the blood pressure may occur without drug intervention. E. V. Allen⁵ who has studied for years the effect of drugs on blood pressure, expresses skepticism about the enthusiastic reports on certain preparations. Factors which produce enthusiasm include "(1) failure of recognition by those who report favorably that the blood pressure of most hypertensive subjects varies greatly and (2) failure of recognition by those who report favorably of the nonspecific effect of any kind of treatment. A third factor may be a difference in the genesis of the hypertension of different groups studied. Fluctuation of blood pressure in hypertension if presented in terms of interpretation that result in reporting the highest figure observed before treatment and the lowest figure after treatment, will give credit to any medicament even a placebo of distilled water. Because anxiety will increase blood pressure the reassurance of repeated conferences with a physician may result in a reduction of pressure that cannot be ascribed to a specific remedy. In presenting criteria for the evaluation of any form of therapy, the author differentiates between hypotensive effects and relief of symptoms, many methods relieve the latter. If these criteria were followed, the author asserts, 'those who treat hypertension would be freed of the state of constant confusion which now exists.'

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

TUBERCULOSIS CONTROL PROGRAM OF THE U S PUBLIC HEALTH SERVICE

SURGEON GENERAL THOMAS PARRAN

U S Public Health Service

Recognizing the special threat of tuberculosis during wartime, the United States Public Health Service established an Office of Tuberculosis Control shortly after war was declared. Although there has been no apparent increase in the amount of tuberculosis in this country the objective circumstances favoring such an increase are much in evidence. Particularly is this true in the many congested war areas.

In addition to maintaining general standards of health and medical care, there are certain specific measures which can be undertaken to prevent a wartime rise in tuberculosis incidence and fatality. These are defined in the objectives of the Office of Tuberculosis Control:

- 1 Chest x-ray examination of workers in war industries, with follow-up of newly discovered cases by state and local health departments

- 2 Extension of this service to families of war workers found to be tuberculous

- 3 Extension of the case finding program of the armed forces to include all recruits of the Coast Guard

- 4 Development of a workable system by which cases of tuberculosis discovered in rejected recruits will be reported promptly to state and city health departments in order that immediate clinical examination, treatment and other care may be provided within the limits of available local resources

- 5 Encouragement and assistance in the establishment of chest x-ray examination procedures in the admitting rooms of general hospitals and state hospitals for the mentally ill

- 6 At the request of state and municipal health departments, rapid inventory of existing control programs, and assistance in the reorganization of such programs in accordance with wartime needs

At the present time the Public Health Service has eight 35 mm photofluorographic units in operation in war industries. In assigning the units, special attention is given to the needs of shipyards, ordnance plants, air depots and other essential establishments where no facilities for chest x-ray examinations are available. The small film units are lent to state health departments for a limited time, primarily to demonstrate the need for such services to get local programs started and to train local personnel. Industrial concerns are encouraged to procure their own equipment and personnel for carrying on the work permanently.

Each unit consists of a medical officer, a technician, a clerk and complete equipment for exposing and proc-

essing from three hundred to five hundred small films per eight hour day. The equipment can be used continuously, three shifts a day, when sufficient personnel is available.

The Public Health Service also has two 4 by 5 inch units available for special projects.

In cooperation with the District of Columbia Health Department one of the small film units is being used in Washington, D C, to make chest x-ray films of government employees. In the first survey of 5,404 employees in one agency, 66 cases of reinfection tuberculosis were discovered by x-ray examination, including 42 minimal, 22 moderately advanced and 2 far advanced cases. Positive cases are reported immediately to the family physician and local health department for clinical study, determination of activity and disposition. It is hoped that during the coming year additional units will be provided to enable the Public Health Service to examine large numbers of government employees.

Orders have just been placed for ten additional small film units, and necessary personnel is being recruited. With twenty units in full operation during 1943, it is hoped that two million chest x-ray examinations will be made by the Public Health Service in cooperation with state health departments.

A consultation staff of part time and full time specialists in the fields of tuberculosis and roentgenology is being developed for service to state and municipal health departments during 1943. The full time consultants, who will be commissioned officers, will make careful inventories of each state program and assist in developing plans to provide care for cases of tuberculosis newly discovered as a result of surveys in industries, war industry communities and routine chest x-ray screening of recruits by the armed forces. Immediate plans include the employment of a specialist in medical records who will analyze control activities on the federal, state and local levels and assist the states in developing adequate systems of follow-up records, which are essential for successful tuberculosis control.

The Office of Tuberculosis Control collaborates closely with the National Institute of Health in its research activities. Some of the material collected as a part of the service program will be used for research into administrative practices. Such close correlation of research and service should shorten the lag between research and the application of its results.

This office works in close cooperation with the Division of Industrial Hygiene of the National Institute of Health, and the National Tuberculosis Association.

Details of the program have been presented at the formal meetings of the national organizations of experts in the fields of tuberculosis and roentgenology.

The support and cooperation of these specialists have been earnestly solicited in order to achieve economy in the use of medical manpower and to avoid duplication of effort.

The increase in tuberculosis mortality in Great Britain is being carefully observed. A significant development was the announcement by the minister of health on Oct 8, 1942 that he has authorized local health authorities to grant financial assistance to families while the bread winner is undergoing sanatorium treatment. This development will bear close watching, because sooner or later we must face the same social and economic problems in this country.

Consultation service to the states in inventory and reorganization of tuberculosis programs is already paying dividends in intensification of case finding among industrial workers and better utilization of limited facilities for inpatient and outpatient care and supervision.

Our principal task now is to extend tuberculosis control activities so as to cover the greatest number of people in the shortest possible time with all available governmental and voluntary resources and personnel.

In addition to preventing an expected rise in tuberculosis mortality during wartime a foundation can be laid for a postwar program which will have for its ultimate objective the eradication of tuberculosis in the United States.

REPORT FROM RUSSIA

[NOTE—From Russia by cable comes this report of the Twenty-Fifth Anniversary Session of the All Union Institute of Experimental Medicine—En]

The Soviet Scientists Antifascist Committee transmits a communication from Prof Nikolai Grashchenko corresponding member of the Academy of Sciences of the Union of Soviet Socialist Republics, reporting on the scientific session of the All Union Institute of Experimental Medicine (VIEM) held in Moscow on the occasion of the twenty fifth anniversary of the great October Revolution. In this session the achievements of the institute in the course of the twenty-five years of Soviet power were summarized in twenty-seven papers. Some of the papers dealt with the problems of army medical service and requirements for protection of health in wartime.

A paper by Professor Vishnevsky and his colleagues demonstrated that certain theoretical concepts when developed clinically are effective in the treatment of thoracic femoral and joint wounds. These were wounds of grave nature requiring long treatment, frequently resulting in permanent crippling and having a high mortality. Correct surgical methods, local anesthesia and use of bandages soaked in Peruvian balsam have given good results in the treatment of serious lesions and in restoring the functions of the organs or the limbs involved. A clinic under the supervision of Vishnevsky gives surgical and medical treatment for serious cerebral and spinal wounds and injuries of the peripheral nerves. This clinic was the first to cooperate with field hospitals in testing the effectiveness of sulfonamide compounds in the treatment of cerebral injuries. We developed a number of original methods in the employment of these drugs such as the 20 per cent emulsion made up of two or three of the sulfonamides, the streptocide, the sulfadine and the sulfrthiazole. This clinic was first to carry out surgical and medical treatment of grave injuries to the spinal column and the spinal cord without encountering such complications as cystitis or bed sores.

The clinic of Professor Chetverikov did pioneer work in investigating pathogenic micro organisms in cerebral injuries, particularly of the role of anaerobic infection and methods of combating it. Professor Sakharov developed a method of restoring function, particularly speech function accompanying cerebral trauma. Prof A Luria in charge of a branch clinic in the Urals devised a method of surgical treatment of trauma to the peripheral nerves. Some conclusions based on more than 700 cases and more than 400 operations were made both for and against surgical methods of treatment. Dr Izratov of the same branch developed methods of restorative therapy for lesions of the peripheral nerves. Rational therapeutic methods making allowance for residual functions of the upper extremities secure restoration of motor function many times more rapidly than by physical therapy and curative gymnastics alone. Prof M Borovsky demonstrated on experimental material the significance of peripheral section of a nerve in genesis

of dystrophic processes. Formation of ulcers in limbs and other trophic disorders are largely associated with a peculiar condition of peripheral section following injury to the nerve. Progression of a dystrophic process can be prevented by injection of 70 per cent alcohol into the distal section of the injured nerve. These data were confirmed by Professor Golub working in a military hospital in the rear. Professor Anokhin discussed results of his theoretical and clinical investigations of formal treated nerve used as a transplant to bridge large defects of injured peripheral nerves. He also reported on advances made in the treatment of neuralgia.

Prof A Bramstein explained the mechanism of action of thiamine on pain. He studied also thiamine hypovitaminosis processes associated with lesions of the central and peripheral nervous system. These data demonstrate the exceptional therapeutic value of thiamine in the treatment of lesions of the cerebrum, the spinal cord and the peripheral nerves. Prof M Shennakin discussed the mechanism of biologic action of vitamin K, which proved to be a powerful agent in increasing the prothrombin content of the blood and decreasing hemorrhages. Professor Smorodintsev reported on methods of early diagnosis of typhus as developed in his laboratory and based on concepts advanced before the war by Prof A I Joffe of the Leningrad branch of the VIEM. He discussed also the specific prophylaxis of typhus. Prof Smorodintsev carried out an experimental and epidemiologic comparative study on three kinds of vaccines: original and modified vaccine, Durin sparrow vaccine successfully developed and introduced into practice by Professor Kravtsovsky and the Cox vaccine. Of exceptional interest were two papers by Professor Petrishcheva on new insecticides in collaboration with an experimental chemotherapeutic prophylaxis of rickettsias. Petrishcheva made use of the immense vegetable resources of western Siberia and waste products of the coal industry to produce very powerful insecticides in the form of emulsions, solutions and powders against lice, bugs and other parasites which spread contagious diseases. In the second study Petrishcheva used lice as experimental object. She infected lice with rickettsias after having saturated them with sulfonamides. Chemotherapeutic effects were then studied.

Bacteriostatic and bactericidal substances were tested on a large scale as anti-septics in infectious diseases and in wound infections. Results of the studies were reported by Professor Ermoleeva. Dr Chumrakov proposed a rapid method of neuro virus encephalitis diagnosis. To prove the virus nature of encephalitis neutralization reaction was previously used. This required however a great number of white mice, shortage of which is now felt and considerable time—one to three weeks. Dr Chumrakov makes use of complement fixation as developed for diagnosis of some children's infections by Professor Joffe and for typhus by Professor Smorodintsev. This reaction proved extremely effective for rapid diagnosis and is accessible to city bacteriologic laboratories.

ARMY

MEDICAL OFFICERS AND ENLISTED MAN
DECORATED FOR GALLANTRY

The War Department has announced the award of the Silver Star for gallantry in action at Semem, New Guinea, on Dec 7, 1942 to seven officers of the Medical Corps and one enlisted man of the Medical Department. The officers were decorated for caring for the sick and wounded and for working "courageously and fearlessly, entirely oblivious of his personal safety, while continually being bombed and strafed by enemy planes." The enlisted man was decorated for similar heroism and for special care which saved the life of an officer.

One of the officers honored was Major Lemuel E Day, who died on Dec 22, 1942. The Silver Star will be presented to his widow, Mrs Lucille Day, who lives at 6142 North Kirkwood Avenue, Chicago.

The other officers cited are Major Parker C Hardin, whose wife, Mrs Catherine S Hardin, lives at 701 Sixth Street, Charleston, Ill., Major Herbert B Shields Jr whose father, Mr Herbert B Shields, lives at 1702 West Cherokee Street, Enid, Okla., Capt Lloyd W Taylor, whose wife Mrs Dorris Taylor, lives at 631 O'Tarrell Street, San Francisco, Capt William F Edwards, whose wife, Mrs Lucy Edwards, lives at 615 Beharrell Avenue, New Albany, Ind., First Lieut Julius I Gutov, whose father, Mr Herman Gutov, lives at 5634 Mt. bury Grand, Detroit, and First Lieut Nathan Brooks, whose wife, Mrs Mary Brooks, lives at 19323 Sorrento Avenue, Detroit.

The enlisted man honored is Sergt Frederick Kosak, whose mother, Mrs Thekla Kosak, lives at 104-46 119th Street, Richmond Hill, Queens, New York City. After detailing his courageous care of the wounded, Sergeant Kosak's citation reads: "Especially noteworthy was his care of Major Daniel K. Edwards previously wounded in action, whom he covered with mattresses and whose life undoubtedly was saved thereby in the hospital tent in which he lay was riddled with projectiles, many being killed and wounded."

HOSPITAL TRAINS

The Surgeon General of the Army in 1939 directed the planning division of his office to submit recommendations for suitable plans for modern hospital trains. According to Lieut Col Thomas N Page, U S Army Medical Corps, in the February issue of *Modern Hospital*, the train that was designed comprised fifteen cars, including a ward car with thirty berths for patients, two ward cars with berths for 32 bed patients each, a standard dining car to feed 300 patients, a standard pullman to quarter the train detachment, standard pullman cars to provide berths and seats for 225 walking sick and wounded patients, a baggage car for supplies and office space for the surgeon. Six of these trains have been procured and are now in service, giving excellent results. The unit car has space for a kitchen, dressings room, dispensary, cook's quarters and officers' quarters. These trains are for use only in the zone of the interior and not in the communications zone. Trains for the communications zones must be made up in their entirety and be able to run on the various railroads encountered.

COUNTY SOCIETY HONORS ITS
MILITARY MEMBERS

The Mecklenburg County Medical Society at Charlotte, N C., honored its thirty members who are in the military forces of the country, January 5, by dedicating a plaque which bears their names. Dr Parks M King, who served as a captain in the medical department of the first world war, dedicated the plaque. Dr King also served as a hospital steward in the Spanish-American War. Following the dedication Capt Samuel Hartman read a paper on jaundice and yellow fever vaccination, and Capt Ed F Hardman and Lieuts F L Blair and Thomas A Brady read a paper on orthopedic problems at the Station Hospital, Morris Field.

ARMY-NAVY E AWARD TO
DAVIS AND GECK

Brig Gen Fred W Rankin, chief consultant in surgery, Surgeon General's Office, U S Army, Washington, D C., and President of the American Medical Association, on January 6 presented the Army-Navy E award to the management and several hundred employees of Davis and Geck, Inc, Brooklyn, manufacturers of sterile surgical sutures, in which work this company has specialized for more than a third of a century. The E award flag and lapel emblems to be worn by every employee of this company were accepted by Mr B F Hirsch, general manager, on behalf of the management, and by Miss Ethel Bagley, on behalf of the employees, most of whom are women. Other speakers during the ceremonies were Comdr P T Crosby of the U S Navy Medical Corps, Hon John Cashmore, president of the borough of Brooklyn, and D L Tilly, president of the Chamber of Commerce of Brooklyn.

PROFESSOR HERMS CALLED TO
ACTIVE DUTY

Prof William B Herms head of the division of entomology and parasitology at the University of California has been called to active duty and assigned to teach tropical medicine at the Army Medical Field Service School, Carlisle Barracks, Pennsylvania. Professor Herms has been a reserve officer for many years and now holds a commission as a lieutenant colonel in the Sanitary Corps.

THE DARNALL GENERAL HOSPITAL

The Darnall General Hospital situated on Herrington Lake between Boyle and Mercer counties in Kentucky, was leased from the state government by the War Department in July 1941 for the care and treatment of the mentally ill in the military service. Construction work on the new building began on July 29, 1941 and was finished on Jan 27, 1942.

The present bed capacity is 272 and a 520 bed expansion is already under construction which should be finished by the end of the month. The main building is a six story reinforced concrete and brick structure designated for the care of 250 mental cases. The expansion consists of six permanent brick structures that will care for 480 additional mental cases, and one 40 bed ward for duty personnel.

The hospital has been named in honor of the late Carl R. Darnall, brigadier general, a distinguished officer of the Medical Corps. The administrative and professional staff consists of the following officers:

Col Clyde C Odom commanding officer
Lieut Col John D Lamon Jr executive officer and chief of the surgical service
Lieut Col Theodore C C Long chief of the neuropsychiatric service
Major James P Sullivan chief of the medical service
Major Joseph K Norris administrative and personnel officer and chief of staff
Major Charles E Nixon assistant chief of neuropsychiatric service
Major William R Calt post engineer
Capt O B McVee registrar and receiving and evacuation officer
Capt Maurice Lev chief of laboratory service
Capt Ira P Burdum assistant surgical service
Capt Marvin A Cox chief of dental service
Capt Ned Feldman post exchange officer
Capt Robert P Kumble ward officer
Capt Robert D Ralph chief of eye ear nose and throat section
Capt Dayton D Salen ward officer
Capt William L Sharp ward officer
Capt George J Sutherland ward officer
Capt Wylie T Steen chaplain
Capt Ronald H Tanner assistant medical service and hospital inspector
Capt Edward S Truber ward officer
Capt William C Taylor medical supply officer
1st Lieut Lester L Burtnick ward officer
1st Lieut Michael B Dunn psychology consultant
1st Lieut Harry I Horsey quartermaster officer
1st Lieut Joe L Luce CO Det medical department
1st Lieut Charles L Meistrloff assistant dental service
1st Lieut J Lloyd Morrow ward officer
1st Lieut Victor H Rosen ward officer
1st Lieut Herman M Serota ward officer
1st Lieut E M C Stamm innance officer
2d Lieut Raymond W Beagles CO Det of patients
2d Lieut Glenn J Bock Jr director of dietetics
Mr Arthur L Wilson chief warrant officer

AVIATION MEDICAL EXAMINERS

The fifth class in aviation medicine for Aviation Medical Examiners to be graduated under the system of training whereby the didactic portion of the course is conducted at the School of Aviation Medicine in Texas and the practical portion at three army air forces classification centers was graduated on Dec 17 1942. Graduation exercises were held at each of the three centers. The list of graduates follows:

ALABAMA
Cecil Howell Blackburn 1st Lieut Birmingham
Lamb Bolton Myhr 1st Lieut Birmingham
John Carey Patterson 1st Lieut Tuscaloosa
Lance Charles Price 1st Lieut Florence

ARIZONA
Sterling P Hoffmann Jr 1st Lieut Tucson

ARKANSAS
Jim McKenzie 1st Lieut Hope
James Otto Pierce, 1st Lieut Marked Tree
Hugh Walter Savage 1st Lieut Little Rock

CALIFORNIA
Nicholas Edward Bailey 1st Lieut Manhattan Beach
Lewis Claude Blackburn 1st Lieut Santa Barbara
Leland Bowman Blanchard 1st Lieut San Jose
William Guerin Bradley 1st Lieut Los Angeles
Arthur Horace Buell 1st Lieut Long Beach
Vincent Michael Downey 1st Lieut Oakland
James Timmons Dresser 1st Lieut Bakersfield
James Edward Feldmeyer 1st Lieut Clovis
Leyon K Giron 1st Lieut Piedmont
Chester Randolph Goddard 1st Lieut Orange
Victor Adam Herrmann 1st Lieut Los Angeles
Cecil Wayne Hoff 1st Lieut San Bernardino
Harve William Jourdan Jr 1st Lieut Los Angeles
Robert Francis Kelly 1st Lieut Los Angeles
Michael Michaels Mishita 1st Lieut Oakland
Marco Robert Rago 1st Lieut Los Angeles

COLORADO
Robert Rehm 1st Lieut Colorado Springs

CONNECTICUT
Donald A Davis 1st Lieut Danbury
William Ernst Furniss 1st Lieut West Hartford
William Peter Goergen, 1st Lieut Danbury
Charles William Neuhardt 1st Lieut New Hartford
Coles Walker Raymond 1st Lieut Litchfield
William Moses Schubert 1st Lieut New Britain

DELAWARE
James Richard Durham Jr 1st Lieut Wilmington

DISTRICT OF COLUMBIA
Theodore C Bedwell Jr Major Washington
Joseph Aloysius Dugan 1st Lieut Washington
John Harry King Jr Major, Washington
Henry Joseph Wegrocki 1st Lieut Washington
Claude Benjamin White Major Washington

FLORIDA
Daniel H Funkenstein 1st Lieut Jacksonville
Elvin Gilmore Neal 1st Lieut Jacksonville
James Robert Nieder 1st Lieut Delray Beach
Donald George Stannus 1st Lieut Miami Beach
Norman H Steiner 1st Lieut Tampa
Dale Sloan Wilson Captain Miami

GEORGIA
William Kendall Jordan Captain Macon
William Colbert Phillips 1st Lieut Richland

IDAHO
Wilford William Beck Jr 1st Lieut Blackfoot

ILLINOIS
Charles E Ahlm Captain Chicago
Edwin Francis Baker 1st Lieut Ashton
Bernard Everett Cohler 1st Lieut Chicago
William Cooley Jr Captain Peoria
Chester Cochran Doherty Major Chicago
Robert Chatterton Fringer Captain Rockford
Jack Tilden Haskins, 1st Lieut Glenview
Clarence Vernard Hodges 1st Lieut, Chicago
Francis John Hultgen 1st Lieut Chicago
David Elmer James 1st Lieut Belvidere
George Peter Kaplan 1st Lieut Chicago
George Jerome Kivdera 1st Lieut Chicago
Harold Thomas Lawler 1st Lieut Peoria
Howard James McNally 1st Lieut Chicago
Charles Louis Noggle 1st Lieut Chicago
Donald Herbert Root Captain Quincy
John Bernard Roth 1st Lieut Morris
Alfred George Schultz 1st Lieut Jacksonville
Tommy Richard Young Captain Mount Carmel

INDIANA
Ralph Emory Barnett 1st Lieut Peru
John Edward Fisher 1st Lieut Clarksburg
Lloyd Markham Headley 1st Lieut Lehanon
Emory Brisco Lett 1st Lieut Loogootee
Joseph Douglas McDonald 1st Lieut Evansville
Jack McKittick 1st Lieut Washington
Robert Wright Owsley Captain Hartford City
James Gaylord Shanklin 1st Lieut Hammond
William Clayton Stafford 1st Lieut Plainfield
Daniel Cody Tweedall 1st Lieut Evansville
William John Warn 1st Lieut Milan
H Haskell Ziperman, 1st Lieut Indianapolis

IOWA
Vail Burdette Adams Captain West Burlington
Clemment Willroth Byrnes Captain Dunlap
Kenneth Marshall Lemon 1st Lieut Council Bluffs
Robert Lee Sells Jr 1st Lieut Iowa City
David Forrest Shaw Captain Britt
Orville Donald Thatcher 1st Lieut Fort Dodge
Paul Edward Tramp 1st Lieut Audubon

KANSAS
John Aldi 1st Lieut Emporia
Guy William Cramer 1st Lieut Parsons
Archibald Fea Dougan 1st Lieut Kiowa
Cecil Edward Petterson Captain Topeka
Francis Adams Thorpe 1st Lieut Pratt

KENTUCKY
Frank Krenning Bo e 1st Lieut Acheson
Max Costlin Captain Louisville
Morton Atherton Cundiff 1st Lieut Somerset
Leo Esbin 1st Lieut Evans
Samuel Glenn Mareum 1st Lieut Irvine
Charles Barbour Wathen 1st Lieut Morganfield
Richard Hunt Weddle 1st Lieut Somerset

LOUISIANA
Sam Fliss Hartman 1st Lieut New Orleans
Ford I MacPherson 1st Lieut Baton Rouge
Orin Vincent Prejean 1st Lieut New Orleans
Herman Rubinstein 1st Lieut New Orleans
Eugene Sullivant Rogers 1st Lieut New Orleans
James Wallace Schonlau 1st Lieut Winnfield
Max Suter 1st Lieut New Orleans
James William Vaudry Captain (N G) Thibodaux
William Benjamin Wiener 1st Lieut New Orleans
Everett John Witt 1st Lieut New Orleans

MAINE
Kenneth Alexander Laughlin 1st Lieut Portland

MARYLAND
Arnold Lewis Field 1st Lieut Baltimore
Milton Gussack 1st Lieut Chevy Chase
Joseph Marshall Keith 1st Lieut Baltimore

MASSACHUSETTS
Alfred Walter Basamania 1st Lieut Holyoke
Harold Brody 1st Lieut Lowell
George William Geiss 1st Lieut Arlington
Roger Dolor Hebert 1st Lieut Chicopee
William McKendree Jefferies 1st Lieut Boston
Edward F Lawler 1st Lieut Lawrence
Walter Ovid McCanimon, 1st Lieut Boston
Howard Nelson Simpson, 1st Lieut Longmeadow

MICHIGAN
William H Anderson Captain Ewen
John Burge Byers 1st Lieut Grand Rapids
Vincent H Carstensen 1st Lieut Detroit
Louis Elmer Doerr Jr 1st Lieut Detroit
Lewis Jennings Geerlings 1st Lieut Fremont
Robert M Heavenrich 1st Lieut Saginaw
William Ramsey Kavanaugh 1st Lieut Kalamazoo
Jerry Hal McVieckle 1st Lieut Detroit
Richard Louis Rapport 1st Lieut Flint
Edward George Seybold 1st Lieut Ann Arbor
Ralph Hunt Sullivan Jr 1st Lieut Lansing
Franklin Lyle Watters 1st Lieut Detroit

MINNESOTA
Wallace C Beckman 1st Lieut Minneapolis
Frederick Martin Graham 1st Lieut Rochester
John William LaBree 1st Lieut Minneapolis
Duncan Voss Luth 1st Lieut Duluth

MISSISSIPPI
James Eddy Coc 1st Lieut Leland
Albert Frederick William Habeesh 1st Lieut Vicksburg
Edmund Arthur Melvin 1st Lieut Gulfport
John Andrew Murfee 1st Lieut Amory

MISSOURI
William Bayne Allen 1st Lieut Kansas City
Walter Baumgarten Jr 1st Lieut St Louis

James Clinton Cope 1st Lieut Lexington
Charles Holloway Lewellen 1st Lieut Kansas City
Warren M Lonergan Captain St. Louis

NEBRASKA
Vernon Krueger Anderl 1st Lieut David City
William Paul Ward 1st Lieut Lincoln

NEVADA
Lin Shecut Felder 1st Lieut Winnemucca

NEW HAMPSHIRE
Edward Donald Aldin Captain Nashua

NEW MEXICO
Leslie Louis Davis 1st Lieut Las Cruces

NEW JERSEY
Dominic Donald Borrelli 1st Lieut Trenton
Charles Plummer Campbell 1st Lieut Westfield
Maxwell Xavier Colby Captain Long Branch
Vincent Gregory Fay Captain Lytton
Morris Cottlieb Captain Ventnor
Angelo Bartholomew Innance Captain Orange
Charles Peter Ringe 1st Lieut Teaneck
John R Ro e Captain Jersey City

NEW YORK
Harry Ageloff 1st Lieut New York
Ralph Edmund Baxter 1st Lieut Brooklyn
Floyd Maurice Breed 1st Lieut Norwich
John A Cooke Jr 1st Lieut Monticello
James Edward Corrigan 1st Lieut Pithouque
Joseph B Crumer 1st Lieut Rochester
Joseph Charles Lira 1st Lieut Niagara Fall
Cortez Ferdinand Inloos Jr 1st Lieut New York
Roland L Faulkner 1st Lieut Schenectady
Dwight R Griffith Captain Delkaville
William Hildebrand Jr 1st Lieut Kenmore
Frank Charles Horik Jr Captain Niagara Falls
Russell Houghton Hooker 1st Lieut New York
Maurice Joseph Keller 1st Lieut New York
Robert Landesman 1st Lieut New York
Manuel Phillip Landmann 1st Lieut Brooklyn
George Harold Koyne 1st Lieut New York
Merwin M Foster 1st Lieut Brooklyn
Howard Robert Lawrence 1st Lieut Medina
Kenneth Bedell Lewis 1st Lieut Rockville Centre
John King Lucas 1st Lieut Staten Island
Francis Dunn Malone 1st Lieut Hempstead
John R Murphy Captain Saratoga Lake
Paul J O Connor 1st Lieut New York

Stanley Frank Ogortzly 1st Lieut Yonkers
Lawrence Louis Politz 1st Lieut New York
Clarence O Peterson Jr 1st Lieut Mount Vernon
John Bruce Plass 1st Lieut Poughkeepsie

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

The *Reichs Gesundheitsblatt* of Oct 14, 1942 contains under the heading 'The Fight Against Disease' seven pages of advice to doctors on combating the plague' (This "advice" has, according to the paper also appeared in leaflet form and may be bought at 15 pfennig per copy from the Reichsverlagsgesamt, Berlin NW 40). It describes in great detail the sources and known ways of spreading the infection and mentions south eastern Russia as one of the regions where plague infested rodents and in particular rats are to be found. From these endemic plague centers the disease may be carried by infected rats in freight trains and in ships to far distant countries. According to the hygienic conditions prevailing there and the numbers and kinds of rats imported, an epidemic will break out among rats with or without a transmission to man by way of fleas and it may even come to the formation of a new and permanent endemic plague center. In some regions, as for instance in southeastern Russia (Astrakhan), other rodents too may harbor the disease, as for instance field mice and ground squirrels.

After giving details of the various forms of the plague, such as the bubonic and pneumonic varieties, the article deals at length with prophylactic measures. It says that whenever possible the infected person should at once be removed to a hospital

but 'if in exceptional cases a removal to a hospital should prove impossible for instance if the hospitals are overcrowded during an extensive outbreak of the plague, the patient must at least be isolated and all unnecessary communications forbidden. Children from houses or families where a case of the plague has occurred must if they have not been put into quarantine, be kept away from school, the Hitler Youth home and Hitler Youth service, as well as from all other children'.

Klinische Wochenschrift Berlin of Oct 24, 1942 in an article by Dr Bruhl on disease of the stomach, says that 'the army of sufferers from stomach diseases has greatly increased in this war'.

As the cause for this increase in the numbers of patients suffering from stomach troubles we must not solely blame the diet (fresh dark bread, cabbage dishes, feeding in communal kitchens). General factors are just as important causes (overwork, vacations irregular way of living and feeding and so on). Thus to eliminate these extragastral harmful influences is an important therapeutic measure. The intensive treatment of sufferers from stomach troubles is particularly important today since valuable working hours are lost through their illness'.

Nieuwsblad van het Noorden Groningen, of Sept 23, 1942 reports that henceforth a great number of medicines will be available only on prescription. Cod liver oil and eau de cologne are among others subjected to these regulations.

According to the *Deutsche medizinische Wochenschrift* Leipzig of July 31, 1942 to secure the necessary technical medical help for the armed forces and the civil population the planned distribution of all persons who have completed or are completing their training as technical helpers or assistants is necessary. According to a decree by the reich minister for the interior, applications for such personnel and their employment must be made solely through his ministry, which will work in collaboration with the Reich Employment Office for Female Vocations (Reichsvermittlungsstelle für Frauenberufe).

The *Zeitschrift für Urologie* Berlin, 1942, contained an article by Dr. Droschl, who works in a surgical ward in a Grez hospital. He states that the increase in the cases of necessary and prescribed sterilization of men has resulted in a heavy extra burden of work for the hospital and made it necessary to simplify the operation. He then proceeds to give details of the operation.

The *Nieuwe Rotterdamse Courant* of Sept. 17, 1942 reports that last May the Department of Social Affairs began an important extension of the scheme for medical service in the schools. For this purpose it was decided to divide the country into districts, each comprising one or more municipalities. This reorganization is at present in full swing. Much can be done in the already existing eleven districts for school medical service as well as in about thirty-five municipal school doctors' services.

It is intended that the school doctors should in future become full time officials. The district services will cover about forty to fifty thousand persons which means that they will have to cope with an average of from six to seven thousand pupils in the kindergartens and the elementary, advanced elementary and technical schools.

At the University of Utrecht a special course of two months has been established for school doctors. Twenty to thirty-five doctors participated in the course this spring. The second course begins in the autumn.

The state is to bear one third of the costs involved in the school doctors' service. The state will also contribute one third of the costs if important improvements have to be made. The rest of the necessary funds must be raised by the municipalities and perhaps even by the provinces.

THE TRAINING OF AUXILIARY HOSPITAL WORKERS

According to an agreement reached in Washington early in January by the Subcommittees on Hospitals and Nursing of the Health and Medical Committee, Office of Defense Health and Welfare Services, the responsibility for employing and training auxiliary hospital workers rests with the individual hospital.

The subcommittees concerned with the coordination of wartime hospital and nursing administration decided that it is neither desirable nor practicable for the federal government to foster a training program for hospital auxiliary workers. Dr. James A. Crabtree, executive secretary of the Health and Medical Committee said 'We feel the problem to be entirely local.'

Some professional groups have contended that the federal government should assume at least partial responsibility for training, placing and subsidizing auxiliary workers in hospitals. The series of conferences held over a period of months to weigh all angles of the proposal culminated in final action at a joint meeting of the hospital and nursing subcommittees on January 9.

CITRUS JUICES RESERVED FOR WAR REQUIREMENTS

Secretary of Agriculture Wickard issued an order January 9, reserving for direct war requirements all citrus juices except unconcentrated grape fruit juice, which also cannot be sold by canners during the remainder of January, February and March, with civilian supplies of this product to be released by canners after this period. The purpose of this regulation is to insure adequate supplies of canned citrus products for government requirements and to conserve tin plate by requiring civilians to use most of these citrus fruits in fresh rather than in canned forms.

TWENTY FELLOWSHIPS IN PUBLIC HEALTH EDUCATION AVAILABLE

The W. K. Kellogg Foundation has made a grant of \$40,000 available to the U. S. Public Health Service for the purpose of providing twenty fellowships in public health education. The training to be given at the University of North Carolina Chapel Hill beginning March 20, 1943 and continuing until March 1944. The summer quarter will be spent in the field. Successful completion of the studies will lead to a master's degree in public health.

Since a shortage of well qualified health education personnel prevails, these courses are being provided to hasten the time when trained personnel will be available.

The fellowships are open to American citizens between the ages of 19 and 40 and provide a stipend of \$100 a month for twelve months tuition fees and travel for three months of field experience. The applicant must pay his own travel to and from the university at the beginning and end of training. The minimum educational qualifications are:

- (a) Bachelor of science degree or its equivalent from a recognized college or university with major emphasis on:
 - (1) The basic health medical sciences such as physics, chemistry, biology and physiology.
 - (2) Education with emphasis on educational psychology.
 - (3) The social sciences.

Persons interested who consider themselves qualified should mail their application for fellowship in health education together with a transcript of their college credits and a small photograph not later than March 1 to the Surgeon General, U. S. Public Health Service, Washington, D. C.

USE OF ROTENONE INSECTICIDE NOW RIGIDLY RESTRICTED

A new federal order has rigidly restricted the use of rotenone insecticides which now may be used only on certain crops against certain insects. Rotenone has become in recent years a popular insecticide for farms, gardens and household use but the former Far Eastern sources of supply have been cut off and only small supplies are coming from South America. Now the finished insecticide must not contain more than 0.5 per cent of rotenone and must not contain any pyrethrum. Any one at the end of 1942 who had more than 500 pounds of rotenone or 5,000 pounds of rotenone insecticide must report to the War Production Board. Dealers must label or tag all packages sold with a statement of the permitted uses and every one involved must preserve for two years complete records of all rotenone handled. Besides certain vegetables the only other permitted use is on cattle against the cattle grub or short nosed cattle louse. The vegetable uses permitted are on peas against pea weevil and pea aphid on beans against Mexican bean beetle on sweet corn against European corn borer, and on broccoli, brussels sprouts, cauliflower, kohlrabi, mustard, kale, turnips and collards for caterpillars and aphids.

ANALYST FOR THE LEND-LEASE ADMINISTRATION

Mr. M. R. Kneiss, executive secretary of the Catholic Hospital Association of the United States and Canada, St. Louis, has been granted a leave of absence by that association to enable him to accept the position of Principal Trade Requirements Analyst for the Lend Lease Administration. The Rev. Alphonse M. Schwitalla, president of the Catholic Hospital Association, announced that the services of Mr. Kneiss were requested by Mr. Edward R. Stettinius, Jr., administrator of the Office of Lend Lease Administration.

CALIFORNIA STATE GAS OFFICER

Dr. Maurice L. Tainter, professor of pharmacology at Stanford University School of Medicine, San Francisco, has been named state gas officer for California by the state council of defense emergency medical service. Dr. Tainter set up the San Francisco gas treatment and protection services for civilian defense.

ORGANIZATION SECTION

OFFICIAL NOTES

COMMITTEE ON STUDENT HEALTH, AMERICAN MEDICAL ASSOCIATION

The Committee on Student Health held its first meeting at Washington D C, January 11 and 12. All members of the committee were present.

Dr Joseph E Ryerfort Princeton N J Chairman
Dr Ruth E Boynton University of Minnesota Secretary
Dr Arlie C Bock Harvard University
Dr Frank B Kelly University of Illinois
Dr O N Anderson Stanford University

Dr W W Bauer, American Medical Association staff, met with the committee.

The committee met first in the office of Col Leonard G Rowntree, chief of the Medical Division of Selective Service, and conferred briefly with Major Gen L B Hershey, director of Selective Service. The committee was entertained at luncheon in Selective Service headquarters in order to meet the following representatives of various government services and other guests, who were as follows:

Major Gen L B Hershey, Selective Service director, Washington D C
Col George Bachr, Medical Division U S Office of Civilian Defense, Washington D C
Col A N Bagg, Medical Division National Headquarters, Washington D C
Col Theodore P Bank, Special Service Division, War Department, Washington D C
Col Lawrence W Long, State director, Mississippi Selective Service System, Jackson, Miss
Col L G Rowntree, chief, Medical Division, Selective Service, Washington D C
Col C R Wells, National Headquarters, Selective Service System (chief Dental Section), Washington D C
Lieut Col Louis H Renfrow, Dental Section, National Headquarters, Washington D C
Douglas D Finch, New York State War Council (Photographic Section), Albany, N Y
Ernest J Jaqua, War Manpower Commission, Washington D C

Hiram A Jones, director, Office of Physical Fitness, New York State War Council
Frank S Lloyd, Federal Security Agency (Division of Physical Fitness), Washington D C
Harlan G Metcalf, Federal Security Agency (Division of Physical Fitness), Washington D C
Watson D Miller, Assistant Administrator, Federal Security Agency, Washington D C
Robert H Owen, Selective Service Headquarters, Washington D C
C C Parker Jr, Selective Service, Washington D C
J R Shuman, Office of Education, Washington D C

An informal discussion of physical fitness and health was held during and after luncheon. Hiram A Jones, director of the Office of Physical Fitness of the New York State War Council, showed a motion picture film descriptive of the statewide program in New York State.

After hearing from Colonel Rowntree and Mr Metcalf of the Federal Security Agency, the committee spent the rest of the day and evening and the next day in discussing and surveying the possible scope of its activities and sources of information as to previous contributions in the field of student health. The following areas to be investigated by various members of the committee were assigned:

1. Information on height, weight and growth of college men and women of today compared with those twenty or more years ago.
2. An analysis and evaluation of physical fitness tests now in use.
3. Information on nutrition of children and standards of nutritional needs.
4. The status of health teaching in colleges, as well as the lower schools and the results of pretesting of young people in the health field.
5. Information to show if possible the comparative health of the nation now and in previous years through the analysis of examinations of men for Selective Service, as well as other sources.

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Bills Introduced—H R 350, introduced by Representative Guyer, Kansas, proposes to prohibit, within the District of Columbia, the manufacture, importation, exportation, transportation, sale, gift, purchase or possession of any spirituous, vinous, malt, fermented and all alcoholic liquors whatsoever which may be used as beverages, except natural wine for religious services, and ethyl alcohol for compounding or manufacturing medicines for internal use and as a disinfectant by physicians, surgeons and dentists in their professions. H R 1567, introduced by Representative Bradley, Michigan, prescribes certain offenses relating to the keeping, injuring and destroying of dogs in the District of Columbia.

MEDICAL BILLS IN CONGRESS

Bills Introduced—S J Res 24, introduced by Senator Capper, Kansas, proposes a constitutional amendment to confer on Congress the power to make laws which shall be uniform throughout the United States on marriage and divorce, the legitimation of children and the care and custody of children affected by annulment of marriage or by divorce. S 65, introduced by Senator McNary, and H R 497, introduced by Representative Angell, both of Oregon, provide for the payment of annuities to blind persons, in an amount not to exceed \$50 per month in case a blind person has an income of less than \$1,200 a year. S 599, introduced by Senator Thomas, Oklahoma, provides that any tuberculous World War veteran whose dis-

ability compensation rating is service connected shall be rated as permanent and total for compensation purposes. S 460, introduced by Senator Capper, Kansas, provides for the uniform regulation of marriage and divorce. Among other things, this bill proposes that no license to marry shall be issued to any person who is insane or an imbecile, proper, epileptic, feeble minded or afflicted with tuberculosis or a venereal disease. S 622, introduced by Senator Walsh, Massachusetts, for himself and Senator Clark, Missouri, proposes to authorize the Veterans' Administration to provide vocational rehabilitation and assistance in securing suitable employment for service connected disabled veterans. S 623, introduced by Senator Walsh, Massachusetts, proposes to extend the federal old age and survivors insurance benefits of the Social Security Act to certain employees of religious, charitable, scientific, literary or educational associations. H J Res 28, introduced by Representative Mundt, South Dakota, and H J Res 36, introduced by Representative Voorhis, California, propose to establish a commission for postwar planning and reconstruction. H J Res 69, introduced by Representative Voorhis, California, proposes to establish the first week in October of each year as "National Employ the Physically Handicapped Week." H R 114, introduced by Representative Voorhis, California, proposes to establish under the Fish and Wildlife Service of the Department of the Interior a research laboratory to study the diseases of domestic rabbits. H R 130, introduced by Representative Bland, Virginia, provides that the fund for the relief of sick

and disabled and destitute seamen belonging to the United States merchant marine service shall also be available for the relief of sick, disabled destitute or needy dependents of deceased seamen H R 639, introduced by Representative Welchel, Georgia, proposes to authorize the Administrator of Veterans Affairs to provide domiciliary care, medical and hospital treatment and burial benefits to certain veterans who were placed on the pension roll by an omnibus bill in 1922 H R 757, introduced by Representative Voorhis, California, provides educational grants in an amount of \$500 per person per year to veterans of the second world war to enable them to continue their education H R 912, introduced by Representative Rankin, Mississippi, proposes to provide liberalized benefits for disabled veterans and their dependents Among other things this bill (1) would extend the benefits of existing law to any officer enlisted man, member of the Army Nurse Corps (female) or Navy Nurse Corps (female) employed in the active military or naval services of the United States on or after Dec 7 1941, and before the termination of the present war, (2) would provide that in granting hospital treatment and domiciliary care for disabilities not shown to be due to military or naval service, the Administrator of Veterans Affairs be directed to give preference to veterans who have been discharged by reason of disability and to veterans entitled to or receiving compensation, pension, or retirement pay for service connected disabilities and (3) would provide for the vocational rehabilitation of veterans H R 979, introduced by Representative Allen, Louisiana, provides that, while hospitalized for service connected disabilities, war veterans shall be rated as totally disabled H R 981, introduced by Representative Bates, Kentucky, provides that, when selecting sites for location of new hospitals or other facilities for use by the Veterans' Administration, due consideration shall be given the prospective number of veterans to be served by such hospitals or facilities and the sites chosen shall be as near the center of each such veteran group as is practicable and most conducive to the health of such group H R 1119, introduced by Representative Peterson, Georgia, provides pensions to peacetime veterans of the Regular Army, Navy, Marine Corps and Coast Guard suffering from arrested tuberculosis contracted while in service H R 1185, introduced by Representative Rankin, Mississippi, proposes to amend Veterans Regulations so as to provide benefits for any officer, enlisted man, member of the Army Nurse Corps (female) or Navy Nurse Corps (female) employed in the active military or naval service of the United States on or after Dec 7, 1941 and before the termination of the present war H R 1293, introduced by Representative Hare, South Carolina, provides that grants-in aid by the United States to any state shall be computed on the basis of the ratio of the per capita income of the United States to the per capita income of such state in lieu of being computed on the basis of equal matching of funds by the United States and the State H R 1509, introduced by Representative Reece, Tennessee, provides that any ex service person shown to have had tuberculosis in a compensable degree and who has drawn a temporary total or permanent and total rating of disability compensation for the tuberculous disease and who is not now drawing a permanent and total rating of compensation but who is drawing the statutory award or rating of disability compensation for tuberculous disease shall hereafter receive not less than \$100 per month which rating shall be continued during the lifetime of the veteran H R 1510, introduced by Representative Sauthoff, Wisconsin, proposes to amend the Social Security Act to provide that aid by states to dependent children who are mentally incompetent irrespective of age, be included in computing grants by the United States to such states for aid to dependent children H R 1566, introduced by Representative Bradley, Michigan, provides for the punishment of persons transporting and receiving certain stolen dogs in interstate commerce H R 1604, introduced by Representative Forand, Rhode Island, proposes to authorize an appropriation of \$1 500 000 to construct a veterans hospital in the state of Rhode Island, with a 300 bed patient capacity, for the diagnosis, care and treatment of general medical and surgical disabilities H R 1723, introduced by Representative Klein, New York, proposes to extend the provisions of the Social Security Act relating to old age and survivors insurance benefits to employees of certain nonprofit organizations

STATE MEDICAL LEGISLATION

Arkansas

Bills Introduced—H 103 proposes to provide \$15 000 to purchase pneumothorax equipment and to pay the fees of physicians for administering pneumothorax treatment to patients certified by the superintendents of the state tuberculosis sanatoriums H 123 proposes to require all persons applying for a marriage license to be examined by a licensed physician to determine the presence of any venereal disease or whether or not such persons are idiots feeble-minded imbeciles epileptic or insane

California

Bills Introduced—S 547 to amend the premarital examination law proposes that certificate forms provided by other states having comparable laws and by the United States Army or Navy for military personnel may be accepted S 596 to amend the Business and Professions Code provides for the examination and licensing of chiropractors and defines chiroprody as the diagnosis medical surgical mechanical manipulative and electrical treatment of the human foot including the non-surgical treatment of the leg No chiropractor may do any amputation or use an anesthetic other than local A 664 to amend the business and professions code proposes the addition of a new chapter to provide for the issuance of licenses to practice physical therapy defined as the treatment of physical or mental conditions by the use of massage therapeutic massage exercise therapeutic exercise, or by the use of the physical chemical and other properties of electricity (except x-rays radium and electrosurgery), heat light or water A 667 to amend the food and drug act proposes to add thyroid to the list of preparations which shall be deemed to be misbranded unless labeled in the required manner A 951 proposes to exempt from taxation the sale of ophthalmic lenses and eyeglass frames and fittings when sold on the prescription of a licensed optometrist

Colorado

Bills Introduced—H 236 proposes the enactment of a relicensing act but excepts therefrom services rendered by chiropractors osteopaths physicians surgeons dentists embalmers nurses, optometrists undertakers, chiropractors, hospital chemists or state licensed veterinarians H 525 proposes to authorize the state board of medical examiners to grant and revoke licenses to practice chiroprody defined as the diagnosis and medical surgical mechanical manipulative and electrical treatment of ailments of the human foot and leg excepting amputation of the foot or leg or the administration of an anesthetic other than local or the reduction of dislocations or fractures Surgical treatment is further defined to mean the surgical treatment of all minor foot or leg ailments excepting the surgery on the bony structure or ligamentous tissues of the foot or leg

Connecticut

Bills Introduced—S 484 to amend the food and drug act, proposes, among other things to limit to emergencies only the dispensing by a physician veterinarian or dentist of amido-pyrine barbituric acid cinchophen dimetophenol or derivatives thereof, and narcotic drugs S 559 to amend the law concerning examinations by school medical advisers, proposes that such medical adviser shall interpret to the school nurse teacher, principal superintendent and to the parents of such pupils his findings at the examination and shall recommend how the pupil should be cared for and what provisions, if any should be made at the school for the care and welfare of the pupil S 562, to amend the law concerning health examination of school children proposes to require physicians who make such examinations to make their recommendations concerning the pupil in writing S 678 proposes a penalty of life imprisonment for procuring an abortion whether the abortion is fatal or not S 782 proposes that chiropractors shall be subject to the rules and regulations governing physicians in making and filing death certificates S 783, to amend the chiropractic law proposes to extend the scope of chiropractic practice to include the location and removal of interference with normal nerve function and the right to prescribe and apply hygienic and sanitary measures incident to the care of the body S 784 to amend the chiro-

practic law, proposes to extend the scope of chiropractic practice to include the locating and removal of interference with normal nerve function by any method not including the use of drugs or surgery and including hygienic and sanitary measures incident thereto. S 785, to amend the chiropractic law, proposes to change the educational requirements from four college years of thirty-six weeks each to four college years of eight months each of not less than three thousand six hundred hours. Substitute for H 312 proposes to appropriate \$50,000 for furnishing medical, hospital, obstetric and pediatric care to wives and children of service men when they are unable to purchase such care for themselves. H 716, to amend the law relating to physiotherapy technicians, proposes to repeal the section setting forth qualifications for registration of physiotherapists without examination. H 718 proposes the creation of a state board of examiners in massage which is defined as any process or action of conjoint motion and pressure applied by hand, such as rubbing, stroking, kneading, tapping or other similar manipulation with or without the application of creams, lotions or liniment or the use of hand vibrators or rollers to any part of the human body for the purpose of relieving pains, aches, stiffness or soreness of muscles or for the purpose of inducing blood circulation or reducing conditions of obesity, or for any other remedial purpose including the use of any and all other manual means such as physical exercises for the conditioning of the human body. H 727 proposes the creation of a board consisting of a psychiatrist, a psychologist and a doctor of internal medicine, a surgeon and a psychiatric nurse or social worker to examine all mental patients prior to commitment to any private or state hospital. H 1026 proposes to authorize the court in certain circumstances to order the examination of an accused person to determine whether or not such person is suffering from a venereal disease and if the result of the test is positive to make such order as may be necessary for the detention and treatment of such person.

Delaware

Bills Introduced—S 38 proposes to authorize the medical council of Delaware to issue temporary emergency certificates to physicians licensed outside the state. S 41 to amend the medical practice act proposes to exempt therefrom the treatment of human ills by prayer or spiritual means in accordance with the tenets of any well recognized religious denomination. S 49 proposes to require all school children to be immunized against smallpox and diphtheria, unless excused by a written statement by a reputable physician.

Idaho

Bill Passed—H 43 passed the House on January 29, providing that each applicant for a marriage license must produce a certificate signed by a licensed physician certifying that the applicant has been thoroughly examined and that he is not infected with syphilis in a communicable stage. The physician making the examination may not charge more than \$2.

Illinois

Bill Introduced—S 21, to amend the traffic laws, proposes that a person shall be deemed, prima facie, to be operating a motor vehicle under the influence of intoxicating liquor whose blood urine, saliva or breath contains more than certain stated percentages of alcohol as determined by a chemical test of such breath or body fluid.

Indiana

Bills Introduced—S 12, to repeal the present vital statistics law and substitute a more complete one, propose among other things, that the term 'physician' as used therein shall mean a person lawfully authorized to practice medicine in Indiana. H 28 proposes the creation of a board of chiropractic examiners to examine and license chiropractors and define chiropractic as the science of locating and adjusting the subluxations of the articulations of the human spine and its adjacent tissues. H 187 proposes the appointment of examiners in physical therapy, defined to mean that part of the practice of medicine dealing with the application to pathologic conditions of the physical forces of heat, light, electricity, thermo and hydrotherapy, massage and medical gymnastics and kinesiologic.

Kansas

Bills Introduced—H 121, to amend the medical practice act, proposes to eliminate the requirement that no two of the required four six month periods which must be spent in the study of medicine and surgery may be given within the same twelve months. The purpose of this bill is apparently to enable graduates of accelerated medical courses to obtain licensure in Kansas. H 138 proposes to require each physician attending a pregnant woman to take a blood sample within fourteen days of the first examination and to submit such sample for a standard serologic test for syphilis. H 139 proposes to require each applicant for a marriage license to produce a certificate from a duly licensed physician stating that such person is not infected with syphilis in a communicable stage. Such certificate shall also state that no abnormalities of an anatomic or physiologic nature have been discovered which in the opinion of the examining physician would contribute to a serious incompatibility and so nearly as can be determined that no insanity, feeble-mindedness or epilepsy exists. The physician's fee for each person shall not exceed the sum of \$2.50.

Bill Passed—H 120 passed the House on February 2. It proposes to excuse physicians in the military service from renewing their license annually and prohibits revocation of such license during such period.

Maine

Bill Introduced—H 124 to amend the divorce law, proposes to authorize the granting of divorces on the ground of insanity.

Massachusetts

Bills Introduced—S 125 to amend the law relating to the commitment of insane persons to state institutions, proposes that no person other than a duly qualified or registered physician in good standing may commit any insane person to a psychopathic institution in the state. H 347 proposes to repeal the law requiring premarital physical examinations and serologic tests. H 352 to amend the law relative to the payment of medical, hospital and other services to dependent children and their parents, proposes to authorize expenses for such services to be paid directly to the person furnishing them when the patient has died or been committed to an institution. H 408 to amend the unemployment compensation law proposes that any person absent from work on account of sickness shall not be debarred from receiving benefits under the law. H 507 proposes to prohibit the sale of contraceptive devices except by a registered pharmacist on prescription by a registered physician and no physician shall furnish a prescription for any device purported to be usable for feminine hygiene except when, in his judgment, a condition of infection, irritation, disease or organic ill necessities or justifies such prescription. H 509 proposes to require every parent or guardian of a minor to keep such minor at home when ill with any of the following diseases: sore throat, common cold, grip, measles, chickenpox, mumps, scarlet fever, whooping cough, chills or fever, stiffness in neck, or rash on body. H 512 proposes certain conditions which an employer of a pregnant woman must comply with, especially with regard to extra rest periods, etc. H 797 proposes to authorize the state department of education to make an investigation and a report including medical opinions thereon, on the toxic effects of meotone and beverage alcohol on school children and youths. H 863 proposes that no person shall be required to submit to vaccination or inoculation of any kind against his will as a condition precedent to attending any public school or institution and that no such certificate of vaccination shall be required for admission to the public schools. Any doctor, nurse or other person who vaccinates or inoculates a child or an adult under guardianship without the written consent of the parent or guardian of said child or adult, will be subject to a fine of \$100 or imprisonment for a year or both. H 866 proposes to authorize the board of health, when it has reason to believe that any person is suffering from syphilis or gonorrhea to cause a medical examination to be made of such person without charge by a qualified physician registered in the commonwealth. H 1198 proposes certain restrictions with respect to the performance of experiments on live animals. In general the proposal authorizes such experiments to be made only by a person holding a license issued by the board of regis-

tration in medicine and only when the experiment is necessary with a view to the advancement of new discovery of physiologic knowledge or knowledge which will be useful for saving or prolonging life or alleviating suffering

Michigan

Bill Introduced—H 102 proposes the creation of a state board of examiners in naturopathy and that licentiates may practice naturopathy as taught by the recognized college of naturopathy

Minnesota

Bill Introduced—H 303 to amend the workmen's compensation act proposes to redefine the word "accident" so as to include "occupational disease, defined as a disease peculiar to the occupation in which the employee is engaged and due to causes in excess of the ordinary hazards of employment, a disease arising out of and in the course of the employment

Missouri

Bills Introduced—S 9 proposes the creation of a state board of naturopathic registration and examination to examine applicants for licenses to practice naturopathy. The system, method or science of treating diseases of the human body, commonly known as naturopathy, and as taught and practiced by the recognized schools of naturopathy, is declared not to be the practice of medicine and surgery. H 45 to amend the law relating to marriage, proposes to require any person applying for a license to marry to furnish a report of a negative laboratory serologic test for syphilis and an affidavit signed by him or herself that he or she is free from syphilis. If the laboratory test is positive, the applicant must present a certificate from a physician licensed to practice in the state of Missouri certifying that the applicant is not infected with syphilis in a communicable stage

New York

Bills Introduced—S 311 and A 362, to amend the law relating to the sale of poisonous, deleterious or habit forming drugs or medicines, proposes that no manufacturer, bottler, packer or wholesaler of drugs shall sell such preparations without being registered. S 335, to amend the domestic relations law, proposes to exempt members of the armed forces from complying with the premarital examination requirements. S 377 and A 493, to amend the labor law, propose to authorize payments of unemployment insurance to persons incapacitated through illness who have previously qualified for benefits. A 97 proposes to define x-ray diagnosis as that method of medical practice in which demonstration and examination of the normal and abnormal structures parts or functions of the human body are made by use of x-rays. Any person, the bill provides, who holds himself out to diagnose or to make any interpretation or explanation by word of mouth, writing or otherwise of the meaning of a fluoroscopic or registered shadow or shadows of any part of the human body made by the use of x-rays or who uses x-rays or radium for the treatment of any human ailment will be deemed to be engaged in the practice of medicine. A 514, to amend the law relating to premarital examinations proposes to exempt from the provisions of such law the granting of a marriage license where one of the parties is in the armed forces of the United States

North Carolina

Bill Passed—H 110 passed the house, January 29. It proposes to authorize state institutions for the care of the sick, feeble-minded or insane to have performed on persons dying in such institution a postmortem examination in the laboratories of incorporated medical schools, after securing the written consent of the decedent person's husband or wife or next of kin

North Dakota

Bills Introduced—S 57 proposes the enactment of a uniform narcotic act. S 63 proposes to prohibit the sale of barbiturals except on a written prescription of a doctor of medicine, doctor of dental surgery or doctor of veterinary medicine lawfully practicing his profession in the state. S 77 proposes to provide for the establishment, maintenance and duties of a district board of health and provides that the district health officer appointed by such board shall be a physician and surgeon regu-

larly licensed to practice medicine and surgery in the state of North Dakota

Bill Passed—S 58 passed the senate on February 2. It proposes to amend the premarital examination law by authorizing the required laboratory test for syphilis to be performed by the state department of health or by any other state public health laboratory approved by the state health officer

Ohio

Bill Passed—S 17 passed the senate on January 26. It proposes to exempt from the operation of the sales tax the sale of drugs or medicine compounded prepared or sold in accordance with or under a prescription issued by a licensed practitioner of medicine

Oklahoma

Bills Introduced—H 175 proposes that no child shall be received or admitted as a pupil at a public school who has not been successfully immunized against smallpox and diphtheria. H 189 proposes to require certain specified types of domestic employees to undergo a physical examination by a licensed physician or a recognized county or city health unit before being employed and annually thereafter

Oregon

Bills Introduced—S 77 proposes to repeal the existing law providing for state reimbursement to hospitals for services rendered victims of motor vehicle accidents. H 71 and H 72 propose the repeal of the existing laws prohibiting driving an automobile while intoxicated. The present law provides that persons arrested and charged with so driving may be taken before a duly licensed physician for examination and that the physician's evidence of such examination may be admitted in evidence at a subsequent trial. H 199 proposes to reenact and extend the existing law providing for state reimbursement to hospitals for services rendered victims of motor vehicle accidents so as to cover ambulance firms. H 222 to amend the chiropractic law proposes to require chiropractors at the time of the annual renewal of their licenses to present proof that they have attended a two day educational program conducted by the Oregon chiropractic association. H 229 proposes to reenact and extend the existing law providing for state reimbursement to hospitals for services rendered victims of motor vehicle accidents so as to cover nurses, doctors and owners and operators of ambulances as well. H 244 proposes the creation of a state board of massage examiners and defines the term massage as the method art or science of treating the human body for hygienic or remedial purpose exclusively by rubbing, stroking, kneading, tapping or rolling the same with the hands or by rubbing, stroking, kneading, tapping or rolling the body with any other agency or instrumentality for the purpose of relieving, alleviating and reducing affected parts thereof

Pennsylvania

Bill Introduced—S 53, a bill to enact an Administrative Agency Law proposes, among other things to prescribe the procedure by which administrative boards may promulgate regulations

Rhode Island

Bill Introduced—H 591 proposes the creation of a board of examiners for electrolysis, defined as the removal of or preventing the growth of the hair on any part of the human body by means of electrical apparatus

Washington

Bills Introduced—S 76 proposes to exempt members of the armed forces from being required to continue in full force and effect their license to practice a profession in the state and provides further that such license shall continue valid if it was valid at the time the licensee entered the service. It may be renewed within six months after an honorable discharge. H 108 proposes to require each applicant for a marriage license to present a certificate from a physician licensed to practice medicine and surgery in the state of Washington or from a physician licensed to practice medicine and surgery in any other state showing that such applicant is free from syphilis in a communicable stage

CALIFORNIA

Dr Halverson Named State Health Officer—The governor has appointed Dr Wilton L Halverson health officer of Los Angeles County as state health officer to succeed Dr Bertram P Brown Sacramento. Dr Halverson who has held the Los Angeles position for more than a year formerly served as health officer of Pasadena for seven years. Born in Litchfield Minn. Dr Halverson graduated at the College of Medical Evangelists Loma Linda in 1929.

Woman Named Director of State Institutions—Mrs Doia Shaw Hefner Los Angeles has been named state director of institutions to succeed Dr Fred O Butler medical director and superintendent of the Sonoma State Home Eldridge who has been acting director since the resignation of the late Dr Aaron I Rosnoff newspapers report. In announcing the appointment Governor Warren is reported to have said that Mrs Hefner has long been identified with institutional probationary and human relations activities in Southern California as an attorney and a doctor of administration of social service. From 1936 to 1938 Mrs Hefner was referee of the Los Angeles Juvenile Court where she is now superior court commissioner.

Psychiatrist Needed—A psychiatrist is being sought by the Los Angeles County Civil Service Commission for a position with the Los Angeles County Hospital to render professional medical services in the diagnosis care and treatment of patients under observation for mental and nervous diseases. Physicians under 55 years of age whether residents of Los Angeles County or not who have graduated with an MD degree from an approved medical school and who have completed at least a one year internship in an approved hospital are eligible for this position. The salary will be \$235 a month. Full information may be obtained from the office of the commission Room 102 Hall of Records Los Angeles and applications must be filed not later than February 17.

Dr Housman Paroled—The San Francisco *Examiner* recently reported that the state board of prison terms and paroles had granted a parole from San Quentin to Dr Nathan S Housman San Francisco effective Dec 18 1942. Dr Housman was charged with failure to keep accurate records of narcotic sales. He entered San Quentin Nov 4 1941 to serve a one to fourteen year sentence for perjured testimony at his trial (THE JOURNAL Dec 13 1941 and Jan 24 1942). The board of prison terms and paroles fixed his sentence at five years and granted him a home and care parole effective after he served eighteen months minus time off for good behavior. When able to work after recovery from a minor operation Dr Housman will take a position approved by the parole board it was stated.

COLORADO

Harvey Sethman Enters Military Service—Harvey T Sethman Denver executive secretary of the Colorado State Medical Society and managing editor of the *Rocky Mountain Medical Journal* for the past fourteen years was called to active duty as captain medical administrative corps, Army of the United States, February 1. He will be on leave of absence from his position with the society for the duration of his military service. Until further notice during Mr Sethman's absence the executive office and staff of the society and its publications including the *Rocky Mountain Medical Journal* will be in charge of the following persons, all of Denver.

Dr John S Bouslog secretary Colorado State Medical Society 537 Republic Building

Dr Lyman W Mason acting editor Rocky Mountain Medical Journal 517 Republic Building

Miss Helen Kearney assistant secretary Colorado State Medical Society and business manager Rocky Mountain Medical Journal 537 Republic Building

The trustees request that addresses for official correspondence and exchange journals be appropriately changed noting that the location and mailing address of the society and its journal remain at 537 Republic Building Denver as in the past.

CONNECTICUT

Edgar Allen Dies—Edgar Allen, Ph D, New Haven, professor and chairman of the department of anatomy at Yale University School of Medicine and director of graduate studies, died, February 3, aged 50, of an acute attack of heart disease reportedly while patrolling the Connecticut shoreline in a Coast Guard auxiliary craft. Dr Allen was born in Canon City on May 2, 1892. He graduated at Brown University in 1915 with the degree of bachelor of philosophy later receiving there the A M, Ph D and Sc D degrees. Assistant in biology at Brown from 1913 to 1915 and assistant in embryology and neurology from 1915 to 1917. Dr Allen served the United States Fisheries Bureau as an investigator at Woods Hole Mass during the summer of 1919 and at Fairport, Iowa during the summer of 1922. From 1919 to 1923 he served at Washington University School of Medicine St Louis first as instructor and then as associate in anatomy and for a time as secretary of the faculty. He became professor of anatomy at the University of Missouri School of Medicine in 1923, serving as dean from 1930 to 1933, when he joined the faculty of Yale as professor of anatomy.

An associate member of the American Medical Association, Dr Allen held memberships in a number of scientific societies including the American Association for the Advancement of Science the Society of Experimental Biology and Medicine American Society of Zoologists Phi Gamma Delta and Phi Beta Pi. In 1941 he was chosen president of the Association for the Study of Internal Secretions and in 1942 president of the American Association of Anatomists for a two year term. He was vice president of the latter group in 1931. During World War I Dr Allen served in the U S Army from May 1917 to February 1919 first as a private and later as a second lieutenant.

He had made extensive contributions to the literature and at one time was a member of the editorial board of *Endocrinology*. Dr Allen made noteworthy contributions to the fields of anatomy and physiology of reproduction and in 1941 was awarded the Babt Medal of the Royal College of Physicians London in recognition of his work on estrogens. With Drs J P Pratt and Q U Newell Dr Allen is credited with obtaining the first unfertilized human ovum to be recovered from the uterine tubes and definitely identified.

DISTRICT OF COLUMBIA

Dr Ives Dies—James E Ives Ph D for many years physician with the U S Public Health Service died January 1 of myriasis received when he was struck by a street car. He was 77 years of age. He was physician in the Office of Industrial Hygiene and Sanitation of the public health service from 1921 to 1931 when he became senior physician. Dr Ives retired in 1936.

Supreme Court Refuses to Assume Jurisdiction on Validity of Birth Control Law—In an opinion which did not discuss the merits of the Connecticut laws the United States Supreme Court February 1, refused to assume jurisdiction to pass on the validity of the Connecticut birth control law because of the circumstances under which the case was presented to it. The case was brought before the Supreme Court by Dr Wilder Tinkston David P Smith clinical professor of medicine Yale University School of Medicine New Haven Conn supported by hundreds of physicians and was an appeal from a decision of the Connecticut Supreme Court of Errors that it was illegal for a physician to prescribe the use of contraceptives even if he believed a married woman's life might be jeopardized by pregnancy. In the recent opinion the Supreme Court said that Dr Tinkston was not the proper person to bring the suit because his own life had not been endangered by the state statutes. The decision of the Supreme Court led lawyers to believe that another proceeding could be instituted by patients asserting that the anticontraceptive laws would jeopardize their lives according to newspaper reports.

ILLINOIS

Sputum Specimen Not Required to Obtain Sulfonamides

—The state department of health has announced that sulfonamide drugs for the treatment of pneumonia will be furnished free to the physicians of Illinois without requiring a specimen of sputum for typing. Physicians will now be able to institute sulfonamide therapy immediately on making a diagnosis of pneumonia. Type specific antipneumococcus serum of necessity will be available only after the type has been determined. At the request of any physician the state department will send from Springfield one bottle of sulfathiazole together with a case report form. On the return of the completed case report indicating that the drug has been used in the treatment of

pneumonia another bottle will be sent. Serum centers and typing stations will continue to distribute serum and sulfonamide compounds under the same policy as in the past and require sputum typing as in the past. The requirement for a sputum specimen, adhered to in the past, was eliminated by the state department of health to conserve the time of physicians in civilian practice whose work has increased.

Meeting of Bacteriologists—The winter meeting of the Society of Illinois Bacteriologists will be held at the Chicago Union February 19. Mr. Howard E. Lind, Chicago, senior bacteriologist, Illinois Department of Public Health, will present a paper on "Observations on Variant Types of *C. Diphtheriae*." John C. Carey, Ph.D., bacteriologist, research laboratory, Hiram Walker & Sons, Inc., Peoria, will read a paper on "Some Factors Affecting the Microbiological Assay for Nicotinic Acid," the co-authors are J. C. Bauernfeind, Ph.D. and Clair S. Boruff, Ph.D., Peoria. Dr. Francis B. Gordon, associate professor of bacteriology, University of Chicago School of Medicine, will read a paper on "Studies on the Problem of Insect Transmission of Poliomyelitis," the co-authors of which are Frank M. Schabel, Ph.D., Harold R. Reames, Ph.D., and Mary E. Snow.

Chicago

Public Forum on Cancer—A public forum on Chicago's cancer problems will be held at the John B. Murphy Memorial Auditorium February 16, under the auspices of the Chicago Cancer Committee, Inc. Dr. Bowman C. Crowell, associate director of the American College of Surgeons, will act as moderator. The tentative program includes the following speakers:

Dr. Ludvig Hektoen, chairman of the committee. The Program of the Chicago Cancer Committee.
Dr. James P. Simonds, Hospital Facilities for Care of Cancer Cases and Instruction on Cancer to Medical Students—Report of New Survey.
Dr. Herman A. Bundesen, Cancer Mortality Statistics in Chicago and the Nation.
Dr. Rollo K. Packard, Relation of the Chicago Hospital Council to the Cancer Problem.
Mary E. Westphal, R.N., director, Visiting Nurse Association of Chicago Home Care of Cancer Cases.
Dr. Alexander Brunschwig, Cancer Research in Chicago.
Mrs. Arthur I. Edison, Local Program of the Women's Field Army.
Dr. Raymond V. Brokaw, Springfield, Ill., subject to be announced later.

A period for questions and answers pertaining to subjects that have been presented will be provided following the discussions.

INDIANA

Educational Conference on Industrial Health—The committee on industrial health of the Indiana State Medical Association will hold a two-day conference on industrial health in Indianapolis, February 25-26, to train physicians for war industries. The program will include the following speakers:

Dr. Carey P. McCord, Detroit, Organization and Cost of Medical Services in Industry.
Dr. Frederick B. Wishard, Anderson, Preemployment Examinations.
Dr. George S. Bond, Indianapolis, Criteria in the Evaluation of Abnormal Hearts.
Mr. Andrew T. Court, Detroit, Comments on Sickness Absenteeism.
Dr. Milton H. Kronenberg, Chicago, Women in Industry.
Dr. Adolph G. Kammer, East Chicago, Tuberculosis Control in Industry.
Dr. Harold A. Vonachen, Peoria, Ill., Syphilis Control in Industry.
Mr. Albert Stump, Indianapolis, Legal Responsibilities of the Industrial Physician.
Dr. Lewis Schwartz, Bethesda, Md., Diagnosis, Treatment and Prevention of Industrial Dermatoses.
Dr. Leroy U. Gardner, Saranac Lake, N. Y., Diagnosis of Silicosis.

The dinner session Thursday evening will be addressed by J. J. Bloomfield, Bethesda, Md., sanitary engineer, U. S. Public Health Service, "Industrial Hygiene in War Production" and Dr. Clarence D. Selby, Detroit, "A War to Win." On Friday a symposium on lead poisoning will be conducted by:

Dr. Robert A. Kehoe, Cincinnati, Experimental Studies on Lead Absorption and Excretion in Human Subjects and Their Relationship to the Diagnosis and Treatment of Lead Poisoning.
Rolla A. Harger, Ph.D., Indianapolis, Measurement of Industrial Lead Exposure by Air Analysis.
Mr. Jacob Cholak, Cincinnati, Measurement of Industrial Lead Exposure by Analysis of Blood and Excreta of Workmen.

A symposium on industrial injuries, with the following participants, will conclude the session:

Dr. Edmond O. Alvis, Indianapolis, Essentials on First Aid and Later Management of Industrial Eye Injuries.
Dr. Sumner L. S. Koch, Chicago, Prevention and Treatment of Hand Infections.
Dr. William V. Woods, Indianapolis, Back Injuries.
Dr. Harold M. Trusler, Indianapolis, Treatment of Burns.
Dr. George J. Garceau, Indianapolis, Treatment of Fractures.

The program is part of a plan whereby the state committees on procurement and assignment and on industrial health may assist industry in solving the medical procurement problems of industry. The entire program is designated as Indiana's Emergency Educational Plan in Industrial Health.

IOWA

New Director of Venereal Disease Control—Dr. Andrew C. Woofert, Hot Springs, Ark., has been assigned to Iowa by the U. S. Public Health Service to direct the state's venereal disease program during the war period. He succeeds Dr. Regnar M. Sorenson, who is now on active duty with the reserve corps of the public health service at the state board of health, Topeka.

Pneumococcus Study Course—The state department of health will conduct a pneumococcus study course in the Medical Laboratories Building, Iowa City, February 16-18, the eighth of these courses to be held in the last four years. Financed by the U. S. Public Health Service, the course will be under the direction of Dr. Milford E. Barnes, Iowa City. Emphasis will be placed on bacteriologic diagnosis, including the Neufeld method and the technique of mouse inoculation.

Eli Lilly Medal Awarded to Harland Wood—The Eli Lilly and Company Research Award for 1942 was presented to Harland G. Wood, Ph.D., since 1936 research assistant in bacteriology at the Iowa State College of Agriculture and Mechanic Arts, Ames, January 28 at a joint meeting of the Iowa State College Branch of the Society of Sigma Xi and the North Central Branch of the Society of American Bacteriologists. Dr. Wood was selected for the award on the basis of his contributions to bacterial physiology. Dr. Wood was born on Sept. 2, 1907, in Mankato, Minn. He received the A.B. degree from Macalester College, St. Paul, in 1931 and the Ph.D. in physiologic bacteriology at Iowa State College in 1935. During 1935-1936 Dr. Wood was the holder of a National Research Council fellowship at the University of Wisconsin. The Lilly award consists of \$1000 and a bronze medal. It is offered by Eli Lilly and Company to a young man or woman under 35 years of age who has made outstanding contributions to knowledge in the fields of bacteriology or immunology while conducting investigative work in a noncommercial research or educational institution in the United States or Canada. The recipient is chosen by an award committee composed of members of the Society of American Bacteriologists, the American Association of Immunologists and the American Society for Experimental Pathology.

KANSAS

Immunization Program in Wichita—The city of Wichita recently conducted a citywide immunization program to protect children against smallpox and diphtheria. The program was sponsored by the Sedgwick County Medical Society, the county and city health departments and the state board of health. About 8000 children received the immunization treatment.

Personal—Mr. Clarence V. Beck, Emporia, has been named the new attorney for the Kansas State Board of Medical Registration and Examination to succeed Mr. Theo. I. Varner, Independence, who is in military service. Mr. Beck was attorney general of the state from 1935 to 1939 and previous to that was county attorney of Lyon County for several terms.

Accidental Deaths—A provisional total of 1349 accidental deaths has been reported for Kansas during 1942. Home accidents accounted for 537 deaths, motor vehicle 365, occupational 228 and public (other than motor vehicle) 219. In 1941 the total of accidental deaths was 1427, with motor vehicle leading with 537, home 517, public (other than motor vehicle) 190 and occupational 183. Comparing the two years as to types of accidental deaths there was an increase of accidental deaths except motor vehicle in which a decrease of 172 was recorded. During 1942 Kansas averaged 1 motor vehicle death a day, the lowest number ever recorded since this study was initiated, according to the *News Letter* of the state board of health.

MARYLAND

Dr. Hussey Named Director of Industrial Hygiene Laboratory—Dr. Raymond Hussey, associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore, and a member of the Council on Industrial Health, American Medical Association, Chicago, has been appointed scientific director of the new Army Industrial Hygiene Laboratory at Johns Hopkins University School of Hygiene and Public Health (THE JOURNAL February 6, page 446). The laboratory will operate under the direction of the occupational hygiene branch of the preventive medicine division of the Office of the Surgeon General of the Army. Dr. Hussey was born in Greensboro, N. C., in 1883 and graduated at Johns Hopkins in 1911. At different times he has been associate in pathology and biophysics at the Rockefeller Institute, assistant professor of pathology at Cornell University Medical College and associate professor at Yale University School of Medicine. He has held concurrent appointments at the University of Maryland School of Medicine and at Johns Hopkins since 1936.

MICHIGAN

Keratoconjunctivitis Made Reportable—The Detroit Department of Health has placed keratoconjunctivitis on its list of reportable diseases, according to *Detroit Medical News*.

New County Health Unit—Approval was given on January 4 to the establishment of a new health department in St. Clair County. The new unit will bring the total of counties in the state having full time health services to sixty-seven, leaving only sixteen counties without these services. The first county health department in the state was established in 1927 in Oakland County.

State Society President Named to Professorship—The board of regents of the University of Michigan recently appointed Dr. Howard H. Cummings, Ann Arbor, chairman of the department of postgraduate medicine and professor of postgraduate medical education. Dr. Cummings was graduated at the University of Michigan Medical School in 1910 and is president of the Michigan State Medical Society.

Personal—Dr. Andrew P. Biddle, Detroit, honor member of the Wayne County Medical Society, was elected president of the Detroit Library Commission at its annual meeting January 5. He has been a member of the commission for seventeen years.—Dr. Martin H. Hoffmann has resigned as director of the psychiatric clinic at Eloise Hospital and Infirmary and head of the county psychopathic parole clinic at Eloise.

MINNESOTA

Dr. Blalock to Give Judd Lecture—Dr. Alfred Blalock, Baltimore professor of surgery at Johns Hopkins University School of Medicine and director of the department of surgery, Johns Hopkins Hospital, will give the tenth F. Starr Judd Lecture at the University of Minnesota Medical School, Minneapolis in the Museum of Natural History Auditorium, March 11. The subject of Dr. Blalock's lecture will be "Traumatic Shock with Particular Reference to War Injuries." The late Dr. Edward Starr Judd, Rochester, an alumnus of the medical school, established the annual lectureship in surgery a few years before his death in 1935.

Minnesota Medicine Observes Twenty-Fifth Anniversary—A special issue of *Minnesota Medicine* in January marked the twenty-fifth anniversary of its founding. The issue contains articles on the development of medicine in Minnesota and the progress of the specialties. The journal had its inception with the appointment of a committee at a meeting of the state medical society in 1916 in Minneapolis. The first issue bearing the title *Minnesota Medicine* was published in January 1918. When the first editor, Dr. Ernest F. I. Richards, St. Paul, resigned in 1919, Dr. Carl B. Drake, St. Paul, was appointed to succeed him and still serves in this capacity.

MISSOURI

Personal—Dr. J. Lee Harwell, Poplar Bluff, was appointed to the city board of health on December 30. Drs. Alfred R. Rowe and Walter L. Brandon, Poplar Bluff, are the other members of the board.—Dr. Carl V. Moore, St. Louis, has been appointed an assistant editor of the new journal *Nutrition Reviews*.—Dr. Elmer E. Glenn, Springfield, was recently chosen president of the Missouri Tuberculosis Association at its meeting in St. Louis.

Ophthalmologists to Return Portion of Fees to Colleagues in Armed Services—Members of the St. Louis Ophthalmic Society recently announced the adoption of a resolution signifying their agreement to remit for the duration of the emergency to every ophthalmologist in the society serving in the armed forces one half of any and all income derived from professional services to patients of the absent physician. Patients will also be encouraged to return to their own physicians when they reenter practice after the war.

NEW JERSEY
